**June 2004**

**Prepared for the  
U.S. Department of Energy  
Idaho Operations Office**

## **ABSTRACT**

This document presents the plan for the closure of the Idaho Nuclear Technology and Engineering Center Tank Farm Facility Tank WM-180 in accordance with Idaho Hazardous Waste Management Act/Resource Conservation and Recovery Act interim status closure requirements. Initial closure activities for Tanks WM-182 and WM-183 served as a proof-of-process demonstration of the waste removal, decontamination, and sampling techniques for the closure of the remaining tanks in the Tank Farm Facility. Such an approach was prudent because of the complexity and uniqueness of the Tank Farm Facility closure. This plan uses the same closure strategy as that used for the Phase I closure of Tanks WM-182 and WM-183, and subsequent tank closure plans. This document describes the closure units, objectives, and compliance strategy as well as the operational history and current status of the tanks. Decontamination, closure activities, and sampling and analysis will be performed with the goal of achieving clean closure of the tanks. Coordination with other regulatory requirements, such as Department of Energy closure requirements, also is discussed.

# **Idaho Hazardous Waste Management Act/ Resource Conservation and Recovery Act Closure Plan for Idaho Nuclear Technology and Engineering Center Tank WM-180**

## **1. INTRODUCTION**

Under the terms of the 1992 Consent Order (and subsequent modifications) between the Idaho Department of Health and Welfare<sup>a</sup> and the Department of Energy (DOE) (IDHW 1992), DOE must permanently cease use of the tanks in its Tank Farm Facility (TFF) at the Idaho National Engineering and Environmental Laboratory (INEEL) Site or bring the tanks into compliance with secondary containment requirements as set forth by Idaho Administrative Procedures Act (IDAPA) 58.01.05.009 (2004) (40 Code of Federal Regulations [CFR] 265.193, 2004). The Consent Order further specifies that this compliance cannot be achieved through an equivalency demonstration or by obtaining a variance as provided by IDAPA 58.01.05.009 [40 CFR 265.193(d)(4) and (h)]. The DOE plans to close the TFF tanks because high-radiation fields would make compliance with secondary containment requirements difficult, and a need for such storage is not evident after 2012.

The TFF includes 11 belowground 300,000-gal and 318,000-gal tanks (hereinafter referred to as 300,000-gal tanks) and four 30,750-gal tanks (hereinafter referred to as 30,000-gal tanks) (see Figure 1). The 300,000-gal tanks are numbered WM-180 through WM-190. The 30,000-gal tanks are numbered WM-103 through WM-106. The second modification to the Consent Order specifies that DOE must cease use of Tanks WM-182, WM-183, WM-184, WM-185,<sup>b</sup> and WM-186 by June 30, 2003, and the remaining tanks by December 31, 2012. Ceasing use of the tanks, as defined in the Consent Order, means that DOE must empty the tanks down to their heels (that is, the liquid level remaining in each tank must be lowered to the greatest extent possible by the use of existing transfer equipment) (IDHW 1998). According to the Idaho Hazardous Waste Management Act (HWMA) (State of Idaho 1983) and Resource Conservation and Recovery Act (RCRA) (42 United States Code [USC] 6901 et seq., 1976), the TFF is an interim status hazardous waste management unit. Because of this, the requirements of 40 CFR 265 (2004) apply to the TFF closure (rather than 40 CFR 264 [2003]).

The TFF tanks will be closed in phases; Phase I includes Tanks WM-182 and WM-183, Phase II includes WM-184, WM-185, and WM-186, and Phase III includes Tanks WM-103, WM-104, WM-105, WM-106, and WM-181. The first three phases are presently in progress. The fourth phase includes the closure of Tank WM-180. The TFF will continue to operate until 2012 while various parts of the facility are being closed. The final closure of any component of the TFF will not be complete until all of the tanks have been closed, the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) (42 USC 9601 et seq., 1980) Operable Unit (OU) 3-14 (TFF soils) record of decision (ROD) is issued, and the CERCLA actions identified in the ROD are complete according to the remedial design/remedial action. The final closure plan will address closure and any required post-closure care of the TFF.

---

a. On July 1, 2000, the Division of Environmental Quality, a division within the Idaho Department of Health and Welfare, was elevated to the State of Idaho Department of Environmental Quality (DEQ). This department now oversees the implementation of the Consent Order.

b. The Consent Order allows Tank WM-185 to be used as an emergency spare tank.

Figure 1. Conceptual overview of the Tank Farm Facility.

Tank closure plans are written with a goal of clean closure; however, a decision to close the unit as a landfill or as clean closure will not be made until final closure.

Two significant releases from TFF piping systems to surrounding soils have occurred. No releases have occurred from the tanks to environmental media. These releases are subject to investigation and remediation as necessary under the INEEL CERCLA program as described in the Federal Facility Agreement and Consent Order (FFA/CO) (DOE-ID 1991).

This closure plan addresses closure of Tank WM-180 including the ancillary equipment, pursuant to the Idaho HWMA and RCRA only. Because the tank also contains radioactive constituents regulated by DOE, the tank also must comply with DOE closure requirements; a DOE closure plan will be developed separately. The DOE requirements are found in DOE Order 435.1, "Radioactive Waste Management" (2001), and its associated guidance and manual (DOE G 435.1-1, 1999; DOE M 435.1-1, 2001). The DOE orders are discussed further in Section 5.1. All closure activities will be closely coordinated to ensure compliance with Idaho HWMA/RCRA and DOE orders.

This document is a plan for the closure of TFF Tank WM-180 as required by IDAPA 58.01.05.009 (2004) and 40 CFR 265, "Interim Status Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities" (2004). This plan describes a strategy for clean closure (removal or decontamination of all waste residues) of the tank to site-specific action levels (ALs). In addition, IDAPA 58.01.05.009 [40 CFR 265.197(c)(1), 2004] specifies that both a closure plan for clean

closure and a contingent closure plan for closure of the tanks as a landfill must be prepared for tank systems that do not have adequate secondary containment. Because the Notice of Noncompliance Consent Order states that the TFF tanks do not have RCRA-compliant secondary containment (IDHW 1992), the contingent landfill closure plan is presented in *Contingent Landfill Closure and Post-Closure Plan for Idaho Nuclear Technology and Engineering Center Tanks in the Tank Farm Facility* (DOE-ID 2003a).

## 1.1 Tank Farm Description

The TFF is part of the INEEL Site's Idaho Nuclear Technology and Engineering Center (INTEC), formerly the Idaho Chemical Processing Plant (CPP). The TFF includes 11 belowground 300,000-gal and four belowgrade 30,000-gal stainless steel tanks. Aboveground structures in the TFF include the TFF Control Houses (Buildings CPP-628 and CPP-619), the Computer Interface Building (CPP-618), valve boxes, and tank and vault sump riser covers. The condenser pits are the TFF belowground structures. The Computer Interface Building is only used to monitor the closure processes and is not otherwise associated with any closure activities. The TFF Control Houses contain piping that is associated with the TFF. Portions of the piping associated with Tank WM-180 will be decontaminated and capped or otherwise sealed during this closure. The condenser pits and tank will be closed during the closure of WM-180. A perimeter fence encloses the TFF (see Figure 2). Buildings border parts of the east and south sides. Gates are located on the west, north, and south sides of the TFF (PSD-4.2, 1998). A description of the INTEC TFF and a general description of the hydrogeologic conditions are provided in Appendix A.

The TFF was used to store liquid wastes generated by spent nuclear fuel reprocessing operations, ancillary operations, and decontamination wastes from reprocessing facilities at INTEC. Construction of the TFF began in 1951 with Tanks WM-180 and WM-181. Tanks WM-182 through WM-184 were completed in 1955, Tanks WM-185 and WM-186 were completed in 1957, and Tanks WM-187 and WM-188 were completed in 1959. The last tanks, WM-189 and WM-190, were constructed in 1964. Construction of the four 30,000-gal tanks was completed in 1955.

Tank WM-180 has five 12-in. diameter risers that provide access to the tank. The risers also have installed equipment such as radio frequency probes for level measurement, corrosion coupons, or waste transfer equipment (steam jets and airlifts). Two steam jets are located inside WM-180. A single steam jet can transfer waste out of a tank at approximately 50 gpm (INEEL 2000a).

Tank WM-180 contains stainless steel cooling coils designed to maintain a temperature that minimizes tank corrosion. The cooling coil network of piping is situated horizontally and vertically on the inside wall perimeter and floor of the tank. The cooling coils were triple rinsed after their last use in the early 1960s.

Tank WM-180 is contained in a concrete vault. The bottom of the monolithic octagonal vault is approximately 45 ft below ground and was placed on bedrock with the walls being poured in place. The 6-in.-thick concrete vault roof is covered with approximately 10 ft of soil to provide radiation shielding.

Liquid waste transfers to, from, and between the TFF tanks are managed through a system of piping, valves, and diversion boxes. The liquid waste is routed through waste transfer valves located in underground, stainless steel-lined concrete boxes, referred to as valve boxes. Liquids resulting from decontamination efforts or leakage of valve boxes and piping encasements (secondary containment for piping) are drained to vaults or diversion boxes (PSD-4.2, 1998).

A centralized vessel off-gas system is designed to maintain negative pressure and balance airflow in each of the 300,000-gal tanks (INEEL 1999). The vessel off-gas piping consists of 12-in.-diameter underground piping from the tanks to condenser pits and then to blowers located in CPP-605; the blowers discharge air to the INTEC main exhaust stack. The components of the vessel off-gas system associated with WM-180 cannot be closed until the tank is grouted because of the safety basis defined in the TFF safety analysis report (SAR-107, 2003), which requires the vessel off-gas system to remain operational until final closure of the tanks.

## 1.2 Waste Description

Wastes stored in WM-180 exhibits the hazardous characteristics of corrosivity (hazardous waste number [HWN] D002) (40 CFR 261, Subpart D, 2004). Historical data indicate the TFF waste exhibited the characteristic of toxicity for lead (D008), cadmium (D006), chromium (D007), and mercury (D009) (DOE-ID 2003b). Also associated with the waste are four RCRA-listed HWNs (Gilbert and Venneman 1999):

- F001 (carbon tetrachloride; 1,1,1-trichloroethane; trichloroethylene)
- F002 (carbon tetrachloride; tetrachloroethylene; 1,1,1-trichloroethane; trichloroethylene)
- F005 (benzene, carbon disulfide, pyridine, toluene)
- U134 (hydrofluoric acid).

## 1.3 Tank Farm Status

The TFF is currently used to (1) store sodium-bearing waste from activities associated with previous reprocessing, ancillary operations, and decontamination activities and (2) receive newly generated liquid waste from INTEC plant operations and decontamination activities. To meet the Settlement Agreement and subsequent court order with the State of Idaho (State of Idaho, DOE, and Department of the Navy 1995), all non-sodium-bearing, liquid high-level waste (HLW) was converted to calcine by February 1998 (DOE 2002). Table 1 summarizes the volumes in the TFF as of April 30, 2004.

Table 1. Tank volumes as of April 30, 2004.

Tank	Volume (gal)	Tank	Volume (gal)
WM-103	615 <sup>a,b</sup>	WM-184	3,000 <sup>a,b</sup>
WM-104	615 <sup>a,b</sup>	WM-185	6,500 <sup>a,b</sup>
WM-105	555 <sup>a,b</sup>	WM-186	6,500 <sup>a,b</sup>
WM-106	558 <sup>a,b</sup>	WM-187	69,200 <sup>a</sup>
WM-180	272,500 <sup>a</sup>	WM-188	258,700 <sup>a</sup>
WM-181	18,700 <sup>a</sup>	WM-189	279,700 <sup>a</sup>
WM-182	6,400 <sup>a,b</sup>	WM-190	500 <sup>a</sup>
WM-183	6,900 <sup>a,b</sup>	<b>Total</b>	<b>930,943</b>

a. Source: Waste Process Computer System, February 27, 2004.

b. These volumes represent rinse water remaining after the tanks were emptied and cleaned.

## **1.4 Maximum Inventory of Wastes**

The provisions in IDAPA 58.01.05.009 (2004) [40 CFR 265.112(b)(3), 2004] require that a closure plan includes an estimate of the maximum inventory of hazardous wastes ever onsite over the active life of the facility. This section discusses the reprocessing operation and wastes generated, tank usage, history of operations, and the maximum inventory in Tank WM-180. The maximum inventory of WM-180 was administratively controlled at 285,000 gal. Details about waste composition and the historical use of Tank WM-180 are located in Section 1.4.4.

### **1.4.1 Reprocessing Operations and Wastes Generated**

Reprocessing operations at INTEC took place from 1952 until they were phased out in 1992. These operations used a three-cycle solvent extraction process to recover enriched uranium from spent nuclear fuel. The spent nuclear fuel was dissolved in hydrofluoric or nitric acid to form a uranyl nitrate solution suitable for solvent extraction. The fuel types included aluminum, zirconium, stainless steel, graphite, and custom. The fuel dissolution process varied depending on the type of fuel to be reprocessed. The enriched uranium was then extracted using a three-step solvent extraction process. The solution remaining after the first extraction cycle was considered HLW and was stored in the TFF. The liquid remaining from the second and third extraction cycles, as well as solutions resulting from decontamination activities, was stored separately in the TFF. This waste is generally referred to as sodium-bearing waste because of its relatively high sodium content (when compared to first-cycle wastes) as a result of decontamination activities. Although reprocessing operations have ceased, the TFF continues to receive waste from INTEC plant operations and decontamination activities.

### **1.4.2 Fuel Dissolution**

Generally, five types of dissolution processes were used during reprocessing because of the varied nature of fuel types: aluminum, zirconium, stainless steel, graphite, and custom. In the aluminum dissolution process, aluminum-based fuels were dissolved in a nitric acid solution in the presence of a mercuric nitrate catalyst. Zirconium-based fuels were dissolved using the fluorinel dissolution process. This process used hydrofluoric and nitric acids, aluminum nitrate, and the soluble nuclear poisons of cadmium and boron. Stainless steel fuels were dissolved in nitric acid while a direct electrical current passed through the fuel in the electrolytic dissolution process. The Space Nuclear Propulsion Program (ROVER) dissolution process was used to dissolve graphite fuels. The ROVER fuels consisted of either an uncoated or pyrolytic carbon-coated graphite matrix that contained uranium dispersed throughout as uranium dicarbide fuel particles. These fuels were first burned in oxygen to remove the graphite. The uranium materials were then dissolved in hydrofluoric and nitric acids. Custom processing in specially designed, pilot plant-type equipment with material-specific dissolvents was used for nuclear material that was incompatible with established dissolution processes. For example, those fuels with nontraditional cladding materials, material impurities, excessively high radiation levels, or small amounts of recoverable fissile material required custom fuel processing methods (WINCO 1986).

### **1.4.3 Fuel Extraction**

In the first-cycle extraction process, uranium was extracted from the uranyl nitrate solution into a solution of tributyl phosphate in dodecane. The aqueous raffinate stream from this extraction, which included the fission products, was sent to the TFF waste tanks unless the uranium concentration remained high enough for further extraction (WINCO 1986).

The second- and third-cycle extraction processes used the hexone extraction process to purify the uranium product from the first-cycle extraction. The process used the solvent methyl isobutyl ketone (hexone) to separate the uranium from residual fission products and transuranic elements such as neptunium and plutonium. The waste material containing the transuranics and fission products was generally evaporated to reduce its volume before being sent to the TFF for calcination (WINCO 1986).

#### 1.4.4 Waste Types and Composition

The types of radioactive liquid waste generated at INTEC can be separated into eight basic categories, as listed below. Table 2 summarizes the typical chemical compositions of these waste types.

- Aluminum waste from the dissolution of aluminum fuels in nitric acid
- Zirconium fluoride waste from the dissolution of zirconium fuels in hydrofluoric acid
- Coprocessing waste that results when dissolver product from aluminum fuel dissolution is used as the complexing agent for zirconium dissolver product before introduction to the extraction system
- Fluorinel waste from the dissolution of zirconium fuels in hydrofluoric acid and nitric acid
- Stainless steel waste from the electrolytic dissolution of stainless steel fuels in nitric acid
- ROVER waste from the dissolution of graphite-type fuels in hydrofluoric acid and nitric acid
- Custom-processing wastes that are the second- and third-cycle raffinates resulting from processing custom fuels
- Sodium-bearing waste that results from process equipment waste evaporator (PEWE) bottoms and sodium-bearing decontamination solutions.

Table 2. Typical chemical composition of various waste types.<sup>a</sup>

Waste Type	Aluminum (M)	Zirconium (M)	Fluorinel (M)	Stainless Steel (M)	Sodium (M)
Acid (H <sup>+</sup> )	1	1.5	1.9	2.5	1.2
Nitrate	4.6	2.6	2.3	3	4.6
Fluoride	0	2.5	2.7	0	0.05
Aluminum	1.3	0.6	0.3	0.65	0.6
Zirconium	0	0.4	0.4	0.01	0.0
Boron	0.01	0.15	0.2	0	0.01
Cadmium	0	0	0.13	0	0.0
Sulfate	0.01	0	0.08	0.06	0.06
Sodium	0.04	0.04	0.03	0.01	1.6
Potassium	0.003	0.007	0.001	0	0.2
Iron	0.01	0.01	0.01	0.06	0.02
Chromium	0	0	0	0.01	0.003
Calcium	0.06	0.02	0.02	0.005	0.04

a. Source: *Idaho Nuclear Technology and Engineering Center Safety Analysis Report* (INEEL 1999).

All first-cycle raffinates were acidic, with a hydrogen-ion concentration between 1 and 3 *M*. Radionuclides in the first-cycle raffinates produced a typical radioactivity level in the stored wastes from 5 to 40 Ci/gal (PSD-4.2, 1998). The raffinates from zirconium dissolution and coprocessed zirconium and aluminum dissolution were fluoride-bearing wastes. The first-cycle raffinates from the dissolution of aluminum and stainless steel fuel were non-fluoride bearing (WINCO 1986).

The chemical and radiochemical composition of the wastes and the amount of heat generated vary with the type of fuel being processed, decay time before processing, and fuel burnup. Chemicals in concentrations up to 4 *M* and large quantities of fission products are present. The major chemicals present are aluminum and nitrate in the non-fluoride waste, and aluminum, zirconium, fluoride, and nitrate in the fluoride waste (PSD-4.2, 1998).

The composition of second- and third-cycle raffinates is essentially the same for all fuel types processed. The fission product activity in these wastes is low enough that little heat is generated, making cooling unnecessary. The principal nuclides present are <sup>137</sup>Cs, <sup>90</sup>Sr, and <sup>238</sup>Pu. The predominant chemicals in the second- and third-cycle combined waste are aluminum and nitrate. The waste is acidic, with a hydrogen ion concentration between 0.1 and 1.6 *M* (PSD-4.2, 1998).

Figure 3 shows the historical volume in Tank WM-180. This volume includes both solids and liquids. The sources and quantities of tank solids are estimated from process history, recent tank-heel sampling, and in-tank video inspections of TFF tanks. The actual amount of solids varies in each tank observed within the TFF. However, based on tank filling history and a comparison of inspected tanks, solid quantities and radiological compositions have been conservatively estimated and should be bounded by this estimate (EDF-1920, 2002). Waste quantities used to calculate inventories in the 300,000-gal tanks were based upon 1 in. of sludge (25% solids and 75% liquid) and about 1/4 in. or 400 gal of free liquid remaining in each individual tank. The quantity of solids sludge from all tanks is estimated to be about 45,000 gal, containing about 86,000 kg of solids (Poloski 2000).

Figure 3. Volumes of waste contained in WM-180.

## 2. CLOSURE OBJECTIVES

This closure plan presents the strategy for clean closure of Tank WM-180 to meet the HWMA/RCRA requirements for cleanup of hazardous constituents only. However, as noted previously, the closure of the tank must also meet the requirements for cleanup of radionuclides to meet the intent of DOE orders for HLW systems, specifically DOE Order 435.1 (2001). A DOE closure plan is being developed that will provide the necessary information for removal of radionuclides. The HWMA/RCRA objectives are discussed in greater detail below.

### 2.1 HWMA/RCRA Clean Closure Objectives

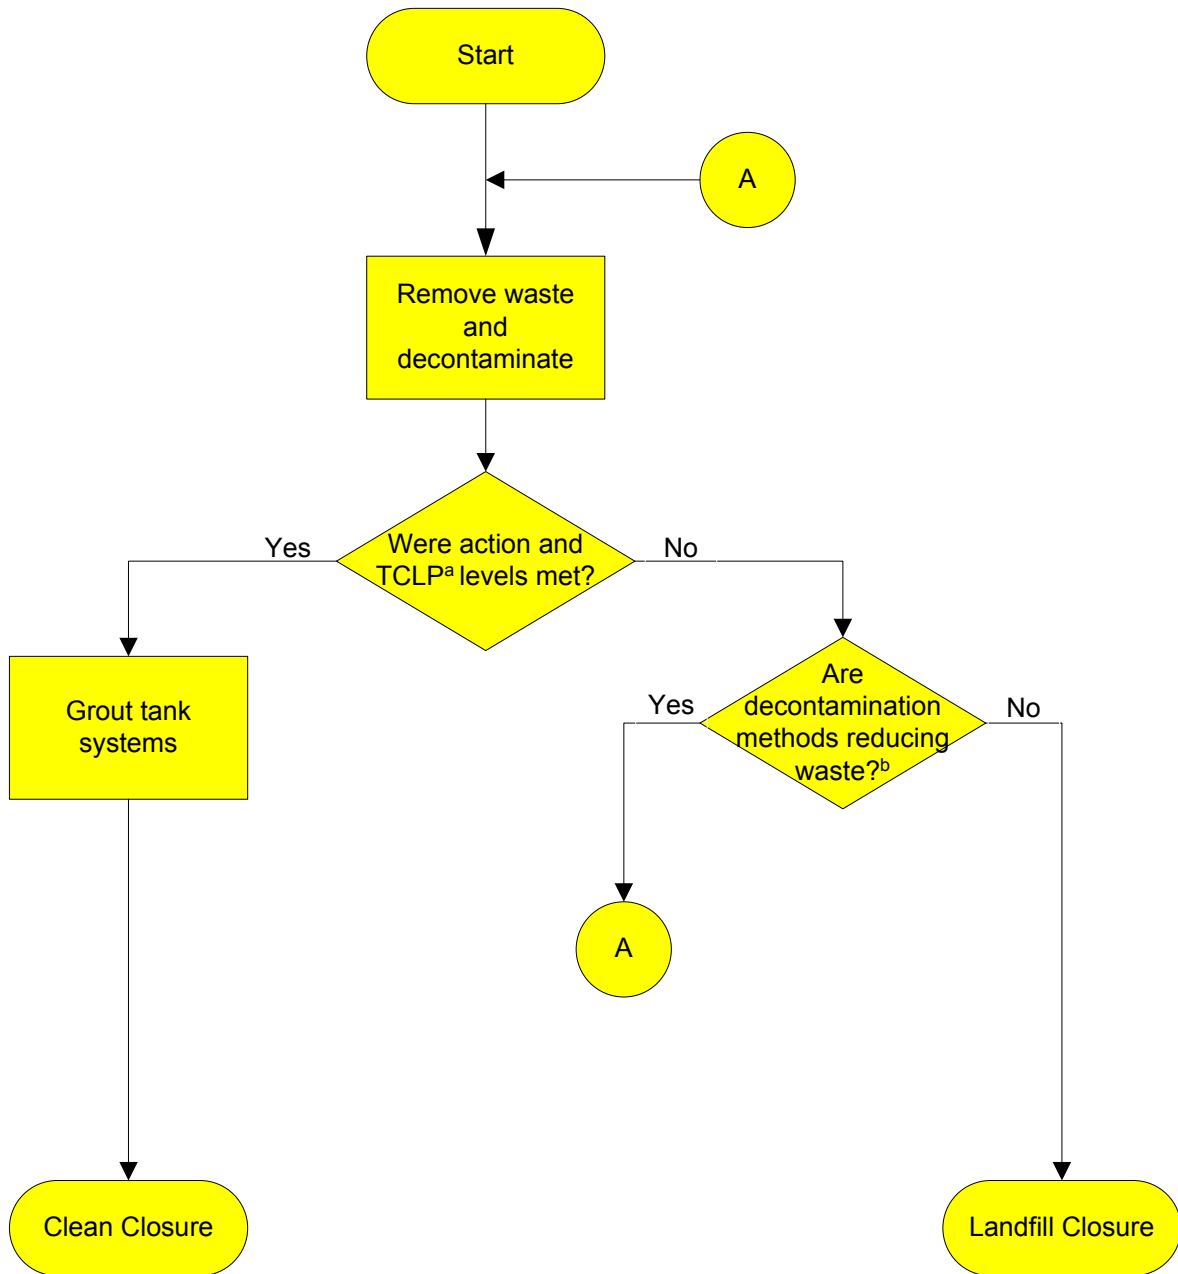

Closure of Tank WM-180 will be performed to meet requirements of both HWMA and RCRA, specifically IDAPA 58.01.05.009 (2004) and 40 CFR 265 (2004). Administrative Rule IDAPA 58.01.05.009 incorporates 40 CFR 265 and all subparts (excluding Subpart R, “Underground Injection,” 40 CFR 265.149, “State Assumption of Responsibility,” and 265.150, “Use of State-Required Mechanisms”) by reference. The objective will be to achieve clean closure of the tank and tank system components in accordance with 40 CFR 265.110, 40 CFR 265.111, 40 CFR 265.112, and 40 CFR 265.197.

Clean closure is the removal or decontamination of all hazardous wastes from the tank system. Except for hazardous waste and liners, the regulations do not require complete removal of all contamination for clean closure. Rather, some limited quantity of hazardous constituents may remain in the tanks after clean closure if the concentrations of hazardous constituents are not RCRA hazardous, are below site-specific ALs, and are protective of human health and the environment. Tank WM-180 is intended to be clean closed. Section 3 describes compliance with the performance standards in 40 CFR 265.111 and 265.197. Figure 4 shows the steps for HWMA/RCRA closure for Tank WM-180.

Although RCRA closure of a tank system requires investigation and removal or decontamination of associated contaminated soils, the contaminated soils investigation and remediation associated with the tank closures will be performed in accordance with CERCLA requirements as described by the FFA/CO (DOE-ID 1991). The entire TFF will be investigated as part of OU 3-14. The investigation is described in the *Operable Unit 3-14 Tank Farm Soil and Groundwater Phase I Remedial Investigation/Feasibility Study Work Plan* (DOE-ID 2003c). The objectives of the remedial investigation as described in the work plan are to collect data for preparation of a baseline risk assessment and feasibility study. The TFF area contaminated soils and the Snake River Plain Aquifer (the area of the aquifer that lies within the boundaries of the INTEC fence) are the focus of the remedial investigation. A final remedial action for the TFF area soils will be the result of the remedial investigation/feasibility study (RI/FS) and subsequent ROD.

To define the clean closure standard, site-specific ALs are developed. The methodology for establishing ALs is located in Appendix B. Clean closure is achieved by performing all of the following steps, as shown in Figure 4:

- Remove or decontaminate hazardous waste. All constituents will be decontaminated to less than the toxicity characteristic threshold concentrations (40 CFR 261.24, Table 1, 2004) and the characteristic of corrosivity (40 CFR 261.22, 2004) and will not exhibit the toxicity characteristic. The pH of the residual will be greater than 2 and less than 12.5, as described in 40 CFR 261.22. Threshold concentrations are not used as ALs but rather to demonstrate that waste does not remain in the tanks.

a. TCLP = toxicity characteristic leaching procedure.

b. This decision will be made after all tanks and ancillary equipment have been closed.

Figure 4. Steps for HWMA/RCRA closure for INTEC Tank Farm Facility tanks ancillary equipment and soils.

- Meet the site-specific ALs described in Section 3.2.
- Meet the performance standards of 40 CFR 265.111 (2004). Grouting of the pipes, tank, vault, and sumps will meet these performance standards to eliminate need for further maintenance and preclude post-closure escape of any residual contaminants during the post-closure period.

## **2.2 DOE Closure Objectives**

The second objective is to meet the closure criteria of DOE Order 435.1 “Radioactive Waste Management” (2001) for Tank WM-180. The DOE closure process is designed to close systems in a manner that is safe and protective of human health and the environment. A Tier 1 DOE closure plan is being prepared to address potential exposure pathways associated with the radiological nature of the tank contents. Before proceeding with the irreversible actions connected to closure, DOE Headquarters will approve the DOE closure plan and issue an Authorization to Proceed. The DOE closure requirements are discussed further in Section 5.1. The methods used for removing radionuclides from the tank systems are the same as those used to meet the HWMA/RCRA requirements described in Section 3.

### **3. CLOSURE REQUIREMENTS AND PERFORMANCE STANDARDS**

Closure requirements are specified by HWMA/RCRA as implemented by IDAPA 58.01.05.009 (2004) and 40 CFR 265 (2004). The matrix in Table 3 summarizes closure requirements and the strategy for complying with the requirements.

#### **3.1 Compliance Matrix**

Table 3 provides a summary of HWMA/RCRA closure requirements for this closure plan, organized by regulatory citation. The table includes a description of how the compliance strategy will meet the requirement and a reference to the section in this closure plan where the strategy is described in more detail. A contingent landfill closure plan has been prepared and submitted (DOE-ID 2003a).

#### **3.2 Action Levels**

The ALs established for WM-180 will be compared to data gathered after final decontamination of the tank and ancillary equipment. Final sample results collected from residuals of the tank and vault will be used as the concentration term, which will be established as the 95% upper confidence limit of the mean of samples collected after decontamination. Residuals from the tank and vault will be sampled. During the course of closure, the data from these samples will be analyzed by statistical methods to determine if the data from the various locations are from the same population. The statistics tests used will be the Student's *t*-test and/or analysis of variance. Potential exposure associated with radionuclide residuals are addressed in the DOE closure plans. The ALs for RCRA/HWMA closure are presented in Table 4. The constituents listed in Table 4 are those that could reasonably be expected to exist in the tank and associated systems. However, hazardous constituents other than those shown in Table 4 that are detected during confirmation sampling (post-decontamination sampling) will be assigned ALs using methodology consistent with that shown in Appendix B.

The ALs were developed by the methodology described in Appendix B. The concentrations of ALs are shown in mg/L. Based on decontamination results from WM-182 through WM-186, it is anticipated that the solid removal will be very effective. Solid sampling and analysis will be in accordance with the *Sampling and Analysis Plan for the Post-Decontamination Characterization of the WM-180* (ICP 2004).

#### **3.3 Soils Strategy**

Soil contamination is present at the TFF because of historical leaks from tank transfer piping. The tanks have never leaked contents to the environment. The RCRA closure of a tank system requires investigation and removal or decontamination of associated contaminated soils. These soils are not part of this plan, however, but are included as part of the OU 3-14 RI/FS. The investigation is described in the OU 3-14 Tank Farm Soil and Groundwater Phase I RI/FS Work Plan (DOE-ID 2003c).

The alternate strategy for removal and decontamination of the tank systems, which includes soils investigation and decontamination, is proposed because the FFA/CO has established that investigations of Solid Waste Management Unit releases are the responsibility of the CERCLA program (DOE-ID 1991). The investigation and remediation plans must be final before closure of the entire TFF. The Idaho Completion Project will plan the soil investigation, with input from the INEEL HLW and HWMA/RCRA regulatory programs.

Table 3. HWMA/RCRA closure plan compliance matrix.

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
<b>§ 265.110 Applicability</b>		
(a) Sections 265.111 through 265.115 (closure) apply to the owners and operators of all hazardous waste management facilities.	These sections are not applicable to this closure.	See citation in matrix below
(b) Sections 265.116 through 265.120 (post-closure care) apply to owners and operators of hazardous waste disposal facilities, waste piles and surface impoundments as required by Sections 265.228 or 265.258, tank systems that are required under Section 265.197 to meet requirements for landfills, and containment buildings as required by Section 265.1102.	Not applicable for clean closure. These sections are addressed in the contingent landfill closure plan (DOE-ID 2003a).	See citation in matrix below
(c) Section 265.121 applies to owners and operators of units that are subject to the requirements of 40 CFR 270.1(c)(7).	Not applicable for clean closure. This section is addressed in the contingent landfill closure plan (DOE-ID 2003a).	See citation in matrix below
(d) The Regional Administrator may replace all or part of the requirements of this subpart with alternative requirements for closure.	Not applicable.	Not applicable
<b>§ 265.111 Closure Performance Standard</b>		
(a) Facility must be closed in a manner that minimizes the need for further maintenance.	The closure strategy results in waste removal and decontamination of Tank WM-180 to ALs to meet clean closure standards, minimizing the need for further maintenance.	2.1, 3.2, Table 4, 4.2
(b) Facility must be closed in a manner that controls, minimizes, or eliminates, to the extent necessary to protect human health and the environment, post-closure escape of hazardous waste, hazardous constituents, leachate, contaminated run-off, or hazardous waste decomposition products to the ground or surface waters or to the atmosphere.	Waste will be removed and the system decontaminated. Only residue that is not RCRA hazardous and does not exceed the clean closure criteria (ALs) will remain in the tank system. Grouting of the tank system will minimize post-closure escape of hazardous constituents, leachate, or hazardous waste decomposition products to the groundwater or to the atmosphere.	4.2, 4.3
(c) Facility must be closed in a manner that complies with the closure requirements of this subpart, including § 265.197 (tank systems).	The closure performance standard will be met as described above. The requirements of § 265.197 will be met as described later in this matrix.	4.2

Table 3. (continued).

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
§ 265.112 Closure Plan; Amendment of Plan		
(a) Written plan. This section specifies the conditions under which a written closure plan must be maintained.	This closure plan meets this requirement. DOE was required under the Second Modification to Consent Order (IDHW 1998) to submit a closure plan to DEQ under the requirements of IDAPA 16(now 58).01.05.009 (40 CFR Part 265, Subpart G) for at least one of the tanks (WM-182 through WM-186) on or before December 31, 2000. The plan will be maintained until closure certification of the facility is provided to the DEQ director.	9
<p>(b) Content of plan. This section specifies requirements for the content of the closure plan:</p> <p>(1) A description of how each hazardous waste management unit at the facility will be closed in accordance with § 265.111.</p>	<p>(1) This closure plan identifies the steps necessary to close Tank WM-180, which is a partial closure of the TFF and INTEC. The general strategy is</p> <ul style="list-style-type: none"> <li>▪ Isolate Tank WM-180 from the rest of the TFF by decontaminating the vault sump; and isolating process lines and the vessel off-gas system</li> <li>▪ Remove steam jet assemblies and radio frequency probes that will not be used during decontamination and corrosion coupons</li> <li>▪ Wash tank walls and agitate tank heels using high-pressure water from a wash ball or similar high-pressure nozzle or nozzle arrangement, simultaneously removing liquids and solids using remaining or newly installed steam jets</li> <li>▪ Decontaminate the vault floor of WM-180</li> <li>▪ Conduct preliminary sampling and analysis of tank residuals after decontamination to determine whether decontamination is complete or whether additional decontamination is required and is economical and practical</li> </ul>	4.2, 4.3

Table 3. (continued).

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
	<ul style="list-style-type: none"> <li>Sample and analyze tank and vault residuals to ensure there is no hazardous waste present and for comparison to ALs</li> <li>Isolate non-process waste lines</li> <li>Perform final heel management and grout tank and components.</li> </ul>	
(2) A description of how final closure of the facility will be conducted in accordance with § 265.111, including the maximum extent of the operation, which will be unclosed during the active life of the facility.	Final closure of INTEC will be performed in accordance with approved interim status or HWMA/RCRA closure plans. A discussion of the maximum extent of operation unclosed is provided in Section 7.	7
(3) An estimate of the maximum inventory of hazardous wastes ever onsite over the active life of the facility and a detailed description of the methods to be used during partial and final closure, including waste removal methods.	The maximum inventory of hazardous waste ever in the tank system is discussed in this closure plan. Liquids and solids, including the tank heels, removed from Tank WM-180 will be transferred to another TFF tank for storage before treatment.	1.3
(4) A detailed description of the steps needed to remove or decontaminate all hazardous waste residues and contaminated containment system components, equipment, structures, and soils.	<p>Ancillary equipment will be flushed with decontamination solution. Piping will be flushed with three volumes of decontamination solution. The tanks will be flushed iteratively with decontamination solution, and residuals will be evaluated to ensure that no hazardous waste is present and compared to ALs to ensure that clean closure criteria will be met.</p> <p>Soil contamination is present at the TFF because of leaks from tank transfer piping. The contaminated soils will be investigated as part of the OU 3-14 RI/FS (DOE-ID 2003c). The FFA/CO has established that investigations of Solid Waste Management Unit releases are the responsibility of the CERCLA program (DOE-ID 1991).</p>	3.3, 4.2, 5.2
(5) A detailed description of other activities necessary during the partial and final closure period to ensure that all partial closures and final closure satisfy the closure performance standards.	No other closure activities have been identified at this time.	Not applicable

Table 3. (continued).

Regulatory Requirement Summary	Compliance Strategy	Section in Plan										
(6) A schedule for closure of each hazardous waste management unit and for final closure of the facility.	Closure schedule (activities may run concurrently)	8										
	<table><thead><tr><th>Activity</th><th>Time for Completion</th></tr></thead><tbody><tr><td>Approval of partial closure plan and DOE Authorization to Proceed</td><td>Day 0</td></tr><tr><td>Remove waste and decontaminate WM-180</td><td>328 days</td></tr><tr><td>Evaluate results, grout and close WM-180</td><td>339 days</td></tr><tr><td>Submit professional 60-day engineer certification (time is in addition to the 1,334 days for closure)</td><td>60 days</td></tr></tbody></table>		Activity	Time for Completion	Approval of partial closure plan and DOE Authorization to Proceed	Day 0	Remove waste and decontaminate WM-180	328 days	Evaluate results, grout and close WM-180	339 days	Submit professional 60-day engineer certification (time is in addition to the 1,334 days for closure)	60 days
	Activity		Time for Completion									
	Approval of partial closure plan and DOE Authorization to Proceed		Day 0									
	Remove waste and decontaminate WM-180		328 days									
	Evaluate results, grout and close WM-180		339 days									
Submit professional 60-day engineer certification (time is in addition to the 1,334 days for closure)	60 days											
<b>NOTE:</b> <i>Waste removal, decontamination, and evaluation will commence on or before approval of the partial closure plan. Grouting will commence after the DOE Authorization to Proceed is received.</i>												
(7) An estimate of the expected year of final closure for facilities without approved closure plans.	Use of the remaining tanks at the TFF must cease by December 31, 2012. The INTEC facility is estimated to be closed no sooner than 2035.	4.2										
(8) This section applies to facilities where the Regional Administrator has applied alternative requirements at a regulated unit.	Not applicable.	Not applicable										
(c) Amendment of plan. This section specifies requirements for amending the closure plan and includes conditions under which the closure plan must be amended, timeframes for providing the amendment, procedures for submitting the amended plan, and procedures for responding to a request for amendment by the regulatory agency.	The closure plan will be amended as necessary in accordance with the requirements of this section.	9										
(d) Notification of partial closure and final closure. This section specifies when the closure plan must be submitted, the date when closure is expected to begin, and how opportunities for public comment on the closure plan will be provided.	Not applicable.	8										

Table 3. (continued).

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
(e) Removal of wastes and decontamination or dismantling of equipment. Nothing in this section shall preclude the owner or operator from removing hazardous wastes and decontaminating or dismantling equipment in accordance with the approved partial or final closure plan at any time before or after notification of partial or final closure.	Closure activities will be performed in accordance with this closure plan.	Not applicable
§ 265.113 Closure; Time Allowed for Closure		
(a) This section specifies when closure activities must begin. The Regional Administrator may approve a longer period under certain conditions, including demonstration that closure activities will, of necessity, take longer than 90 days to complete, and demonstration that all steps have been taken and will continue to be taken to prevent threats to human health and the environment, including compliance with all applicable interim status requirements.	<p>DOE is requesting an extension to the 90-day waste removal period. An extension is required because waste removal activities will, of necessity, require longer than 90 days. Complicating factors include</p> <ul style="list-style-type: none"> <li>▪ The highly radioactive wastes stored in the tank will require that much of the sampling and waste removal work be performed using remote handling technology, which will require significant lead times to set up and conduct</li> <li>▪ The approach for partial closure of TFF tanks in sequence will require the continued availability of storage space in other tanks and treatment capacity in INTEC waste treatment systems for the wastes generated; operational problems in these systems could result in delays in the closure process</li> <li>▪ Closure to ALs will involve an iterative process of decontamination, sampling, analysis, data review, and possibly, additional decontamination.</li> </ul> <p>Tank WM-180 is to be closed because high-radiation fields would make compliance with secondary containment requirements difficult and a need for such storage is not evident after 2012; however, all steps have been taken and will continue to be taken to prevent threats to human health and the environment.</p>	8

Table 3. (continued).

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
(b) This section specifies when partial and final closure activities must be completed. The Regional Administrator may approve a longer period under certain conditions, including demonstration that partial or final closure activities will, of necessity, take longer than 180 days to complete, and demonstration that all steps have been taken and will continue to be taken to prevent threats to human health and the environment from the unclosed but not operating hazardous waste management unit or facility, including compliance with all applicable interim status requirements.	<p>DOE is requesting an extension to the 180-day closure period to 667 days. An extension is required because closure activities will, of necessity, require longer than 180 days. Complicating factors include</p> <ul style="list-style-type: none"> <li>▪ The highly radioactive wastes stored in the tank will require that much of the sampling and waste removal work be performed using remote handling technology, which will require significant lead times to set up and conduct</li> <li>▪ The approach for partial closure of TFF tanks in sequence will require the continued availability of storage space in other tanks and treatment capacity in INTEC waste treatment systems for the wastes generated; operational problems in these systems could result in delays in the closure process</li> <li>▪ Closure to ALs will involve an iterative process of decontamination, sampling, analysis, data review, and possibly, additional decontamination.</li> </ul> <p>Tank WM-180 is to be closed because high-radiation fields would make compliance with secondary containment requirements difficult and a need for such storage is not evident after 2012; however, all steps have been taken and will continue to be taken to prevent threats to human health and the environment.</p>	8
(c) This section specifies when demonstration of conditions requiring an extension must be made.	The demonstrations necessary for extension of the closure periods requested are being submitted in this closure plan.	8
(d) This section specifies when the Regional Administrator may allow an owner or operator to receive nonhazardous wastes in a landfill, land treatment, or surface impoundment.	Not applicable.	Not applicable
(e) This section imposes additional requirements on the owner or operator of a hazardous waste surface impoundment that is not in compliance with the liner and leachate collection system requirements.	Not applicable.	Not applicable

Table 3. (continued).

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
§ 265.114 Disposal or Decontamination of Equipment, Structures, and Soils		
During the partial and final closure periods, all contaminated equipment, structures, and soil must be properly disposed of or decontaminated unless specified otherwise in 40 CFR 265.197, 265.228, 265.258, 265.280, or 265.310. By removing all hazardous wastes or hazardous constituents during partial and final closure, the owner or operator may become a generator of hazardous waste and must handle that hazardous waste in accordance with all applicable requirements of 40 CFR 262.	All contaminated equipment, structures, and soils generated during closure of the tank system will be characterized, stored, and treated in accordance with applicable IDAPA 58.01.05.006 (2004) (40 CFR 262, 2002) requirements.	6
§ 265.115 Certification of Closure		
This section specifies the schedule and procedure for submitting the closure certification. The certification must be signed by the owner or operator and by an independent registered professional engineer.	Within 60 days of completing closure of the tank system, a certification that the tank system was closed in accordance with the specified activities and closure performance standards of the approved closure plan will be submitted to the DEQ director.	10
§ 265.197 Closure and Post-closure Care		
(a) At closure of a tank system, the owner or operator must remove or decontaminate all waste residues, contaminated containment system components (liners, etc.), contaminated soils, and structures and equipment contaminated with waste, and manage them as hazardous waste. In addition, the requirements of 40 CFR Part 265 Subpart G (Closure and Post-Closure) and Subpart H (Financial Requirements) must be met.	<p>The closure strategy developed for the tank system will meet this regulatory requirement. Subpart G requirements are discussed in detail earlier in this matrix. Pursuant to Section 265.140(c), the federal government, as owner of Tank WM-180 is exempt from Subpart H requirements.</p> <p>Soil contamination is present at the TFF because of leaks from ancillary equipment, but contents never leaked to the environment from the tanks. The contaminated soils will be investigated as part of the OU 3-14 RI/FS (DOE-ID 2003c). The FFA/CO has established that investigations of Solid Waste Management Unit releases are the responsibility of the CERCLA program (DOE-ID 1991).</p>	4, 11

Table 3. (continued).

40 CFR, Part 265, Subpart G (2004) Interim Status Treatment, Storage, and Disposal Facility Standards—Closure and Post-closure		
Regulatory Requirement Summary	Compliance Strategy	Section in Plan
(b) This section specifies when closure and post-closure care must be performed in accordance with requirements for landfills. If the owner or operator demonstrates that not all contaminated soils can be practicably removed or decontaminated as required in Section 265.197(a) above, then the owner or operator must close the tank system and perform post-closure care in accordance with the closure and post-closure care requirements that apply to landfills (40 CFR 265.310).	This section applies to the closure of WM-180. This requirement is addressed in the contingent landfill closure plan (DOE-ID 2003a), which covers all the TFF tanks.	Contingent landfill closure plan (DOE-ID 2003a)
(c) This section imposes additional requirements for a tank system that does not have secondary containment that meets the requirements of 40 CFR 265.193 (“Containment and Detection of Releases”), including the preparation of a contingent plan for complying with 40 CFR 265.197(b) above.	This section applies to the closure of WM-180. This requirement is addressed in the contingent landfill closure plan (DOE-ID 2003a).	Contingent landfill closure plan (DOE-ID 2003a)

Table 4. Clean closure action levels for Tank WM-180.

Constituent of Concern (Inorganic)	Action Level (mg/L)	Constituent of Concern (Organic)	Action Level (mg/L)
Aluminum	3.1E+03	Acetone	9.9E+02
Antimony	6.3E+01	Benzene	3.7E-01
Arsenic	4.2E-01	Bromomethane	1.2E+02
Barium	8.3E+01	Carbon disulfide	9.9E+02
Beryllium	5.3E+00	Carbon tetrachloride	2.9E-01
Cadmium	6.1E-01	Chloroethane	9.6E+00
Chromium	9.0E-01	Chloromethane	4.5E+00
Cobalt	7.7E+02	Cyclohexane	7.5E+03
Copper	6.0E+02	Cyclohexanone	7.0E+03
Fluoride	7.7E+02	2,4-dinitrophenol	1.4E+02
Iron	1.7E+03	Ethyl acetate	3.0E+03
Lead	4.0E+00	Ethyl benzene	9.9E+02
Manganese	4.9E+02	2-hexanone	6.3E+02
Mercury	1.6E-01	Methanol	2.2E+03
Nickel	4.4E+02	Methylene chloride	6.0E+00
Selenium	8.9E-02	Methyl ethyl ketone	1.6E+02
Silver	3.0E+00	Methyl isobutyl ketone	8.9E+02
Thallium	2.6E+01	N-nitrosodimethylamine	7.3E-02
Vanadium	2.6E+02	Phenol	2.4E+03
Zinc	1.7E+03	Polychlorinated biphenyl (Aroclor 1260)	3.7E-01
		Pyridine	4.3E+00
		Tetrachloroethylene	4.5E-01
		Toluene	1.4E+03
		1,1,1-trichloroethane	4.4E+02
		Trichloroethylene	4.1E-01
		Xylene	4.4E+03

## 4. CLOSURE STRATEGY

The decontamination activities in Tank WM-182 and WM-183 have been completed, including the sample collection and analysis of the verification samples required in the *Sampling and Analysis Plan for the Post-Decontamination Characterization of the WM-182 and WM-183 Tank Residuals* (INEEL 2002). Decontamination and sampling has also occurred in Tanks WM-184 through WM-186. Because that cleaning has been successful, the same closure strategy will be used for WM-180. Since valve boxes associated with WM-180 will be required for future waste transfers from other non-closed tanks, no valve boxes will be closed during this phase. The closure strategies are discussed in the following sections. During closure, an independently registered Idaho professional engineer (PE) will review activities, data, closure methodologies, and waste management practices.

The Tank WM-180 closure strategy is designed to meet the clean closure requirements described in Section 3. The waste will be removed from the tank, piping, and WM-180 vault. The tank, vault, and piping will then be decontaminated. Following decontamination, sampling and analysis will be performed, followed by data validation, data evaluation, and comparison of toxicity characteristic leaching procedure levels and ALs. Grouting of the tank, tank vault, and piping can occur when the data indicate that hazardous waste is not left in place and concentrations of hazardous constituents are not RCRA hazardous and below ALs.

For WM-180, waste removal under closure will begin when additional water is added to the tank (flushing water) and then removed in conjunction with full-scale decontamination. Process waste lines will be rinsed. New steam jets are planned to be installed and lowered to within approximately 1.0 in. of the tank floor to enhance waste removal. This level is much lower than that of the original steam jets. The remaining residual will be decontaminated by spraying high-pressure water to clean the tank walls, agitating the heel, and pumping the resulting liquid and solid (to await further treatment) to another tank. Grout placement, which is not a part of the residual removal process, is being done to stabilize residuals and remove remaining free liquids. The grouting will minimize the escape of remaining residual contamination as described above.

As required by 40 CFR 265.111, "Closure Performance Standard" (2004), decontamination of the tanks and ancillary equipment will be followed by grouting of the tank, vault, and piping to minimize post-closure escape of hazardous constituents by stabilizing the residuals in a solid matrix. Furthermore, process piping will be capped (thus sealing any residues in the pipes) to minimize escape of hazardous constituents. Samples will be collected from the WM-180 vault to determine if decontamination will be required. The simplified closure sequence to be used for WM-180 is shown in Figure 5. Waste can only enter the pipe encasement between the valve box C-7 and the vault through leaks in transfer piping. There is no record of leaks or spills from any of the piping and no reason to expect RCRA-hazardous waste to be present. Therefore, decontamination of the encasement is not required. Following decontamination, sampling and analysis will be performed, followed by data validation, data evaluation, and comparison to toxicity characteristic leaching procedure levels and ALs. Grouting of the tank, vault, and piping can occur when the data indicate that hazardous waste is not left in place and concentrations of hazardous constituents are not RCRA hazardous and below ALs.

Figure 5. Simplified closure sequence for Tank WM-180.

## 4.1 Facility Closure

IDAPA 58.01.05.009 (2004) and 40 CFR 265.112(b)(7) (2004) state that an estimate of the expected year of final closure for facilities without approved closure plans should be provided. The HWMA/RCRA facility is the TFF, which must cease use of the remaining tanks by December 31, 2012. The INTEC facility has a future use projection "...that in 50 years the INTEC would be approaching the end of useful life if no new mission is identified" (DOE-ID 1995). It is estimated that the INTEC facilities will be closed no sooner than 2035. The following paragraphs provide a description of the closure unit boundaries.

Closure of Tank WM-180 constitutes a partial closure of the TFF. Tanks WM-182, WM-183, WM-184, WM-185, and WM-186 have been decontaminated and will no longer be in operation. The remainder of the TFF tanks will continue to operate during the closure actions. Because Tank WM-180 may share associated piping and ancillary equipment with other tanks in the TFF, the definition of the tank and related components, or more specifically, the tank systems being closed, is necessary.

For the purposes of this closure, the WM-180 tank system is comprised of Tank WM-180 (VES-WM-180), Vault CPP-780, and ancillary equipment such as piping and pumps. Piping will be cut and capped upstream of the CPP-780 vault; valves will be isolated. Other ancillary equipment termination points included in the WM-181 tank system closure are pipes to Valve Boxes C3 (DVB-WM-PW-C3), C4 (DVB-WM-PW-C4), C11 (DVB-WM-PW-C11), and C40 (DVB-WM-PW-C40). Figure 6 shows the WM-181 tank system to be decontaminated for closure. Figure 7 shows ancillary equipment that will be taken out of service during closure but will not require decontamination because it has not contacted hazardous waste. Examples of ancillary equipment that did not contact hazardous waste include equipment installed but never used, the supplied air or steam supply to the tank system, and the equipment used for instrumentation connections.

The CPP-712 building contains the steam, water, air, and instrumentation lines for Tank WM-180. The CPP-738 building contains the cooling coil lines. These buildings also contain similar equipment for other TFF tanks not being closed as a part of this closure plan. Piping and valves associated with Tank WM-180 will be capped in these buildings. Appendix C contains a piping list for closure of Tank WM-180. Table C-2 shows piping and conduit that do not require decontamination or closure.

The following line and equipment designators are used in Figures 6 and 7:

- DVB—diversion valve box
- HSA—high-pressure steam
- PLA, PUA—process waste lines
- PWM, DC-AR—decontamination or transfer line
- RVP—Relief Valve Pit
- SP1, ST1, MP1, MT1—cooling solution return line
- SP0, ST0, MP0, MT0—cooling solution supply line.
- SR—sump riser
- TR—tank riser
- TWN—sensor lines.

## **4.2 Closure**

### **4.2.1 General Closure Activities**

For Tank WM-180, the high-pressure water from a wash ball (or similar high-pressure nozzle or nozzle arrangement to wash the tank walls and agitate the tank heels) will be used to rinse the tank, remove waste, and decontaminate the tank. The decontamination fluid for WM-180 closure will be demineralized water. Water will be obtained from water sources near the TFF. Liquids and solids will be removed using the steam jets simultaneously with wall decontamination and heel agitation. The liquids and solids removed from Tank WM-180 will be stored in an existing TFF tank to await treatment. A video camera and lighting will be installed to monitor and record removal and decontamination efforts. For activities where hazardous constituent contamination may exist, confinement (e.g., temporary enclosures and high-efficiency particulate air [HEPA] filter structures) will be placed to minimize contamination spread.

The ancillary equipment to the tanks consists of piping, trenches, and condenser pits. Table 5 provides an overview of the ancillary equipment and Appendix C lists the piping associated with the closure of WM-180. Not all of the ancillary equipment in the following description will be closed (decontaminated and grouted) during this phase of closure. Some equipment has never contacted hazardous waste, while other equipment is not scheduled to be closed during this phase of closure. For example, the process line 4" PWM-380011Y shown in Figure 7 has never been used. In addition, some ancillary equipment needed for operating tanks cannot be closed. WM-180 has five tank risers. These risers are contained within vault risers that are part of the tank vault. The tank risers will be

decontaminated and grouted. The vault risers, for which there is no record of releases of hazardous waste, will be grouted as part of the vault.

Tank WM-180 uses numerous piping routes to transfer waste solutions, vessel off-gas, and high-pressure steam to and from each tank. Valves housed in diversion valve boxes or condenser pits are used to manipulate all piping transfer routes to and from the TFF tanks. Only the piping shown in green in Figure 6 and listed in Appendix C are to be closed during this phase of the TFF closure.

Table 5. Ancillary equipment associated with WM-180.

Equipment Designator	Description	Comments
TR-15	Tank Riser for WM-180	Decontaminate and grout
TR-16	Tank Riser for WM-180	Decontaminate and grout
TR-45	Tank Riser for WM-180	Decontaminate and grout
TR-46	Tank Riser for WM-180	Decontaminate and grout
TR-47	Tank Riser for WM-180	Decontaminate and grout
SR-16	Sump Riser for Vault CPP-780	Decontaminate and grout
RVP-WM-VG-5	Pressure Relief Pit	Decontaminate and grout

#### 4.2.2 Tank Isolation and Decontamination of Ancillary Systems

The following discussion outlines the sequence of activities required to isolate Tank WM-180 from the rest of the TFF to allow closure activities to take place. The remainder of this section also describes the decontamination of ancillary systems associated with Tank WM-180. The decontamination of ancillary systems is generally sequenced based on a logical progression that ensures decontaminated areas will not be recontaminated by subsequent operations. Generally, the sequence of activities is:

- Process waste line decontamination and isolation
- Removal of system components and installation of cleaning equipment
- Non-process waste line isolation
- Tank decontamination.

The activities have been segregated into stages based on construction logic. The decontamination sequence may change based on field conditions. These decontamination sequence changes would not jeopardize the closure performance standards, would be considered minor deviations, and would be noted by the independent PE during certification. Therefore, sequence changes would not require an amendment to the closure plan.

Cleaning operations will begin with process lines and end with the steam jet lines required to remove decontamination fluids displaced during the initial grout placements in the waste tanks. This logical progression through lines and equipment ensures that cleaned areas will not be recontaminated as cleaning operations continue within the closure boundaries. Figures 6 and 7 and Appendix C show the closure equipment and piping.

**4.2.2.1 Process Waste Line Decontamination and Isolation.** Process waste lines to be closed will be isolated in valve boxes. Split-flow valve cartridges may be installed to replace various valves on process waste lines. This will enable grout to be placed in the lines leading to the tanks while

allowing decontamination and subsequent grouting of lines leading to other portions of the TFF. Split-flow valve cartridges were designed to isolate pipelines without having to manually and/or remotely cut and remove pipe sections in contaminated areas. Use of these cartridges limits worker exposure and minimizes pipe cutting and welding in hazardous environments. A split-flow valve cartridge replaces the ball valve components with a separating plate.

Process waste lines will be flushed with three volumes of water, which will be drained to the tank. Flushing with three volumes of water has been successfully used to decontaminate piping in the TFF to remove residual waste from piping, reduce radiation fields, and limit the potential for airborne radioactivity.

Historically, successful decontamination of the lines has been performed during maintenance and repair work on the systems (i.e., valve replacement or repair requiring welding of lines). During the performance of repairs, the lines were decontaminated. The process used water flushing through the lines from a decontamination connection inside the TFF Control House. When the lines were cut in preparation for welding and visually inspected, the lines were observed to be free of liquids and loose solids (Demmer 1996).

Because the piping systems of Tank WM-180 are very similar to Tanks WM-182 and WM-183, the analysis of samples from the piping in Tanks WM-182 and WM-183 is judged to be representative of piping lines in Tank WM-180. Therefore, the pipes will be rinsed but no additional pipe samples will be collected.

**4.2.2.2 Vault Decontamination.** Approximately 100 gal of decontamination fluid will be introduced into the vault sump removed with the steam jet to the PEWE. An additional 100 gal of fluid will be added and samples will be collected from the sump. Remaining liquids will be transferred using the steam jets to the PEWE. This process will determine if additional decontamination of the vault is required. Sampling of the vault sump will provide sufficient data to characterize the vault (the sump is the lowest point within the vault). If analysis of the samples determines that the concentrations of contaminants of concern are above the ALs, additional decontamination fluid will be added through the tank risers TR-16, TR-47, and/or TR-46 to further decontaminate the vault.

Data from various locations, such as the tank vault sump and tank, will be evaluated using statistical techniques. Several different statistical methods will be applied to the TFF closure data. There are two primary objectives with regard to the statistical analysis of the data. The first objective is to determine if the constituents of interest are present in levels greater than the specified AL. The second objective is to determine if the contents of the tank and the vault sump come from the same population. The description of the proposed statistical analysis is presented in Appendix D.

**4.2.2.3 Removal of System Components and Installation of Cleaning Equipment.** After the covers are removed from the risers using standard INTEC procedures, liquid level indicators and corrosion coupons installed in the tanks will be removed and managed in accordance with applicable regulations as discussed in Section 6.3. Steam jets will be left in the tank for use in the decontamination process.

Tank instrumentation lines for Tank WM-180 will be isolated from each line in the TFF Control House. Two 2-in. electrical conduits that carry 24 thermowell instrumentation lines to the tank will be cut inside the TFF Control House. The portions of these conduits inside the building will be disposed of appropriately, and the portions leading to the tanks will be permanently capped.

**4.2.2.4 Tank Decontamination.** For Tank WM-180, the existing steam jets are 12 in. off the bottom of the tank. Therefore, a new steam jet is planned to be installed and lowered to within approximately 1.0 in. of the tank floor to enhance waste removal. The steam jet will be used to pump out as much of the tank heels as possible. The washing system described in the *Conceptual Design Report, INTEC Tank Farm Facility Closure* (INEEL 2000a) will be used to agitate the heels to allow more effective waste removal in Tank WM-180. The solids will be suspended in liquid by the agitation as demonstrated by the decontamination of Tanks WM-182 through WM-186.

The steam jet will not be removed at the end of decontamination but will be effectively decontaminated by removing thousands of gallons of decontamination fluid from the tank. If the tank liquid does not contain hazardous waste and meets specified ALs, it will be concluded that the steam jet will also be decontaminated. The tank heel will be sent to another existing tank within the TFF. The steam jets will be operated during washing to remove waste residues. Video systems will be used to evaluate and record the effectiveness of the tank wall decontamination. The sampling and analysis approach is described in detail in the sampling and analysis plan (SAP) (ICP 2004).

The initial tank washing sequence is designed to remove contaminants and provide incidental pH adjustment of the heels. The final pH in the decontaminated tank residuals will be confirmed to be greater than 2.0 but less than 12.5.

During tank decontamination, a visual inspection using the remote camera will be made to ensure that the tank walls and floor are clean. A radiation detection instrument will be used to measure radiation levels of waste removed from the tank. When the concentrations of radionuclides are reduced and begin to stabilize, the effectiveness of further decontamination will be minimal. At that point, decontamination will cease. The correlation of removal efficiency between radionuclides and metals in the tank will be sufficient to determine when decontamination efficiency has been maximized.

The data collected from sampling the residuals will be used to determine if the decontamination was successful. Successful decontamination is defined as removing hazardous waste and meeting the criteria described in Section 2.1. If the concentrations of contaminants exceed the ALs, decontamination will continue until the process is no longer economical or practical. Landfill closure will be determined at final closure of the TFF.

### **4.2.3 Sampling of Tank Residuals and Ancillary Equipment**

At the conclusion of decontamination activities, samples of tank residuals will be collected to determine the concentrations of hazardous constituents remaining in the tanks. Samples will be obtained using a pump or other sampling device to be installed in a tank riser. These results will be used to determine if all hazardous waste has been removed from the tank and to compare to the ALs. As the concentrations of radionuclides are reduced and stabilized, decontamination will cease. Samples of the rinsate solution representing the composite of the vault floor will be collected from the vault sump.

The samples will be analyzed in accordance with the SAP (ICP 2004) for hazardous constituents and radionuclides in accordance with DOE closure plans. The sample data will be used to determine if clean closure objectives have been reached. The sample data for hazardous constituents will be compared to the ALs. If the ALs have not been reached, decontamination may resume if it is determined further efforts are likely to be successful. The sampling and analysis approach is described in detail in the SAP (ICP 2004).

All sample data from the tanks and ancillary equipment will be examined to determine if they are from the same population. The statistical analysis to determine if the data are from the same population is

included in Appendix D. The 95% upper confidence level around the mean of each population will be used to compare to the contaminant-specific AL. The ALs are shown in Table 4; the methodology for calculation is explained in Appendix B.

### **4.3 Grouting Activities**

After tank isolation activities are completed, a determination has been made regarding the effectiveness of decontamination, and decisions for DOE closure and HWMA closure have been made, final heel management and tank grouting will begin. At that time, the WM-180 tank vault will be isolated and final grouting of the tank system, including the vault, will be performed. The decision for landfill closure will be determined based on results from all tanks in the TFF. Physical access to some areas does not allow for piping to be grouted. Figures 6 and 7 show the pipes that will only be decontaminated or capped.

#### **4.3.1 Final Heel Management and Initial Tank Grouting**

Grout delivery equipment will be installed through tank risers on Tank WM-180. Video surveillance equipment also will be installed through risers on the tank. Grout will be placed in the tank in layers following a predetermined sequence. The first grout layer will be placed in a manner that displaces as much of the remaining tank residuals as possible, moving the remaining residual toward the steam jet for removal from the tank. As the grout is placed, the remaining tank residual (liquid and solid) will be pumped using the steam jets remaining in each tank and transferred through process waste piping to storage in another TFF tank to await further treatment. After the initial grout placements to remove residuals, the tank will be filled with grout to approximately 4 ft.

Steam supply lines (1.5 in.) will be cut and permanently capped. Dry grout or another absorbent may be placed in the tank if free liquids remain. Video inspection will be used to determine if free liquids remain and if additional absorbent is necessary.

#### **4.3.2 Final Grouting**

The final grouting will include grouting the pipe encasements. Grout will be pumped through the encasement covers. This process will grout over the 1-in. encasement drain lines. Vault instrumentation lines will be capped in the TFF Control House. The lines will then be permanently capped.

The vault for WM-180 will be filled with grout from the vault risers. The grout will be placed in lifts. After the vault has been filled, the vault risers will be filled to the bottoms of the vault riser lids.

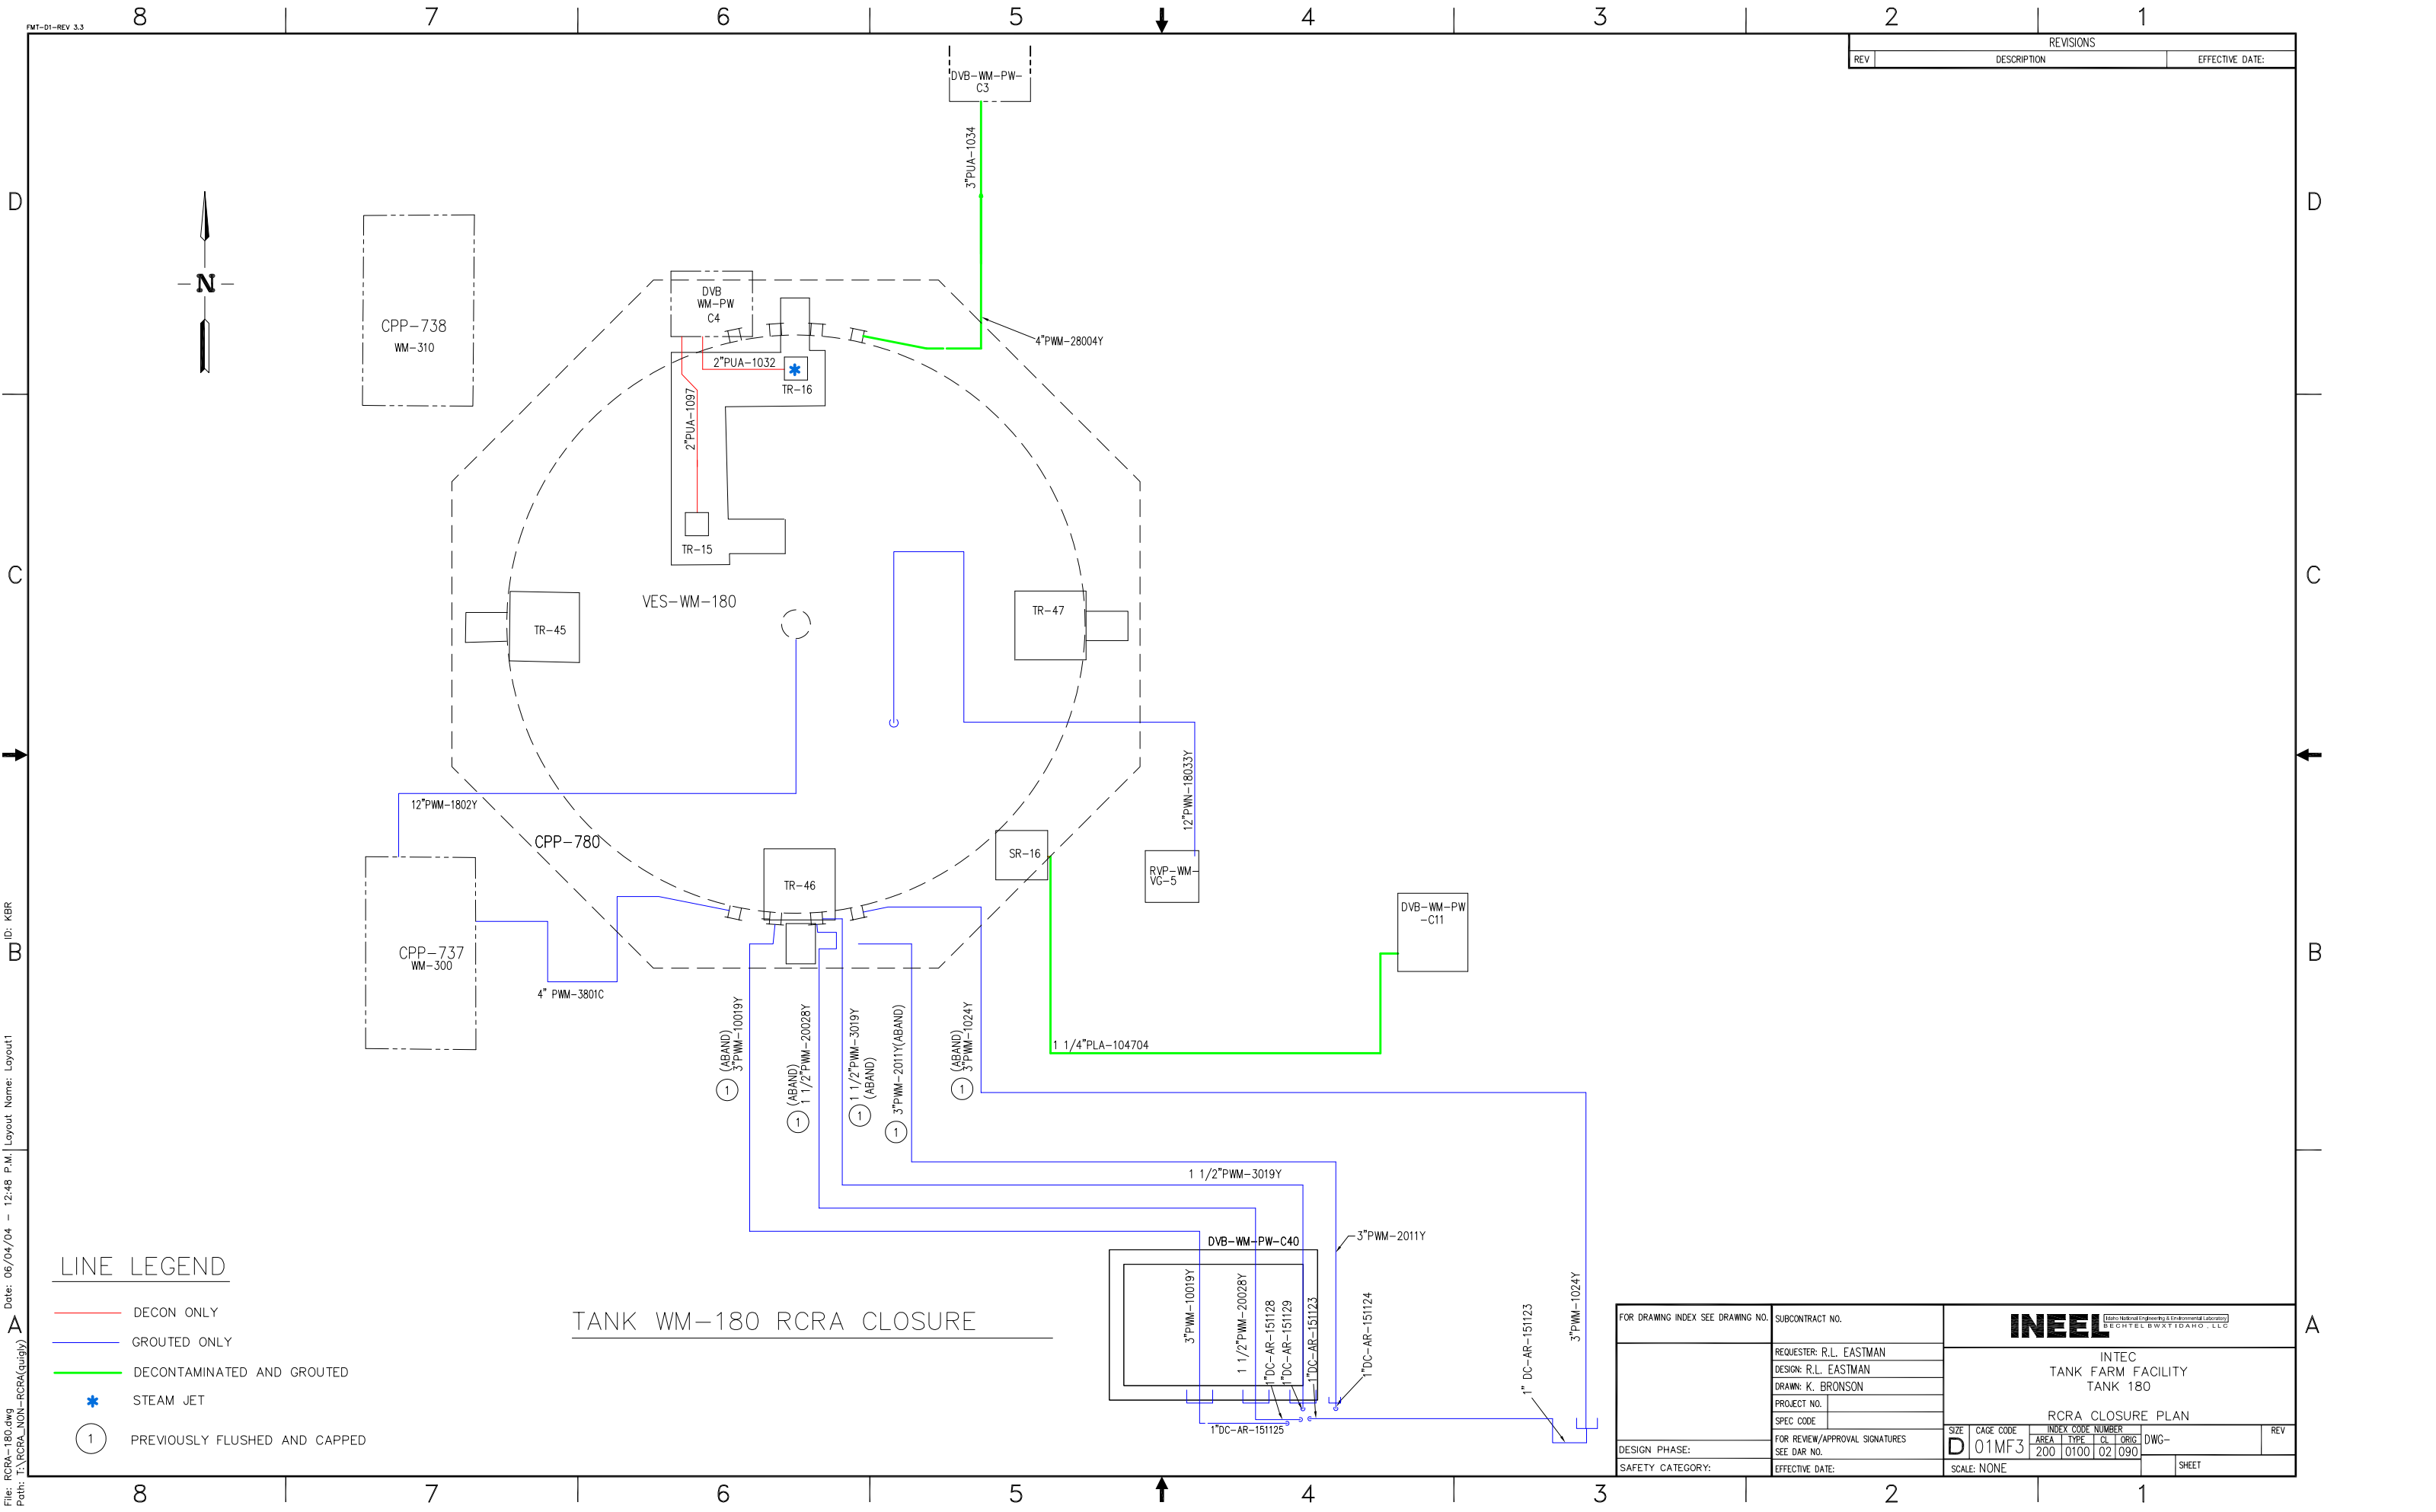

The cooling coil lines for the tank will be grouted by connecting the grouting equipment to the cooling coil headers. Grout will be pumped into each line until it comes out the return end or until the line no longer accepts grout. Supply and return ends of each cooling coil header will then be permanently capped. Process piping lines, as noted in Figure 6, will be grouted in a similar process.

The large tank void remaining after the initial grout placements to remove residuals will be filled with grout, which will be placed in lifts until the tank is full. Video surveillance equipment and lighting will be installed in the center-most tank risers to observe grout placement. The grouting equipment will be reinstalled on the outermost tank risers.

The vessel off-gas lines will be grouted. The grouting equipment will be connected to the lines and grout will be pumped through these lines until grout enters the tank risers. This action will also grout the ends of the PEWE lines that connected the tank. After the remaining tank voids and the vessel off-gas lines are filled with grout, the lines will be permanently capped.

Remaining voids in the tank risers will be filled with grout. The tank riser access boxes will be filled with grout and the tank riser access box covers will be reinstalled.

Grouting completion concludes the closure process for Tank WM-180. Closure-generated wastes will be disposed of as described in Section 6. The closure process will be documented and certified as described in Section 10.

## 5. COORDINATION WITH OTHER REGULATORY REQUIREMENTS

As an interim status hazardous waste management unit, the TFF must comply with applicable HWMA/RCRA regulations. However, the TFF is also a HLW facility regulated by DOE and must meet DOE closure requirements. In addition, other ongoing INTEC and TFF actions may also affect the TFF HWMA/RCRA closure activities. These actions include the CERCLA cleanup of the TFF soils and decisions made pursuant to the *Idaho High-Level Waste and Facilities Disposition Final Environmental Impact Statement* (DOE 2002). Therefore, this HWMA/RCRA closure will be carefully coordinated with each of these other requirements to ensure that the objectives of all activities at the TFF are met efficiently and economically.

### 5.1 DOE Radioactive Waste Management Requirements

Because the TFF is an HLW facility regulated by DOE, this closure must meet the requirements of DOE Order 435.1 (2001) and its associated guidance and manual (DOE G 435.1-1, 1999; DOE M 435.1-1, 2001). Closure requirements for HLW facilities are specified in DOE Manual 435.1-1 (2001). The TFF will be closed under an approved DOE closure plan, in accordance with DOE Order 435.1.

The DOE requires a two-tiered approach to closure plan development, review, and approval. The Tier 1 closure plan will be based on preliminary information and define and bound the parameters of the closure action. The first-tier plan will include the following:

- Closure methodology
- Schedules and assumptions
- Closure standards and performance objectives (for the radioactive constituents)
- Strategy for allocating closure standards and performance objectives to individual facilities and units to be closed at the site
- Preliminary assessment of the projected performance of each unit to be closed relative to the allocated performance objectives
- Preliminary assessment of the projected composite performance of all units to be closed at the site
- Alternatives (if any)
- Waste characterization data
- Closure controls plans
- Stakeholder concerns.

The DOE Tier 1 closure plan is being prepared and will be reviewed by DOE Headquarters. Once DOE Headquarters approves the plan, they will issue an Authorization to Proceed. Cleaning of the tank can proceed before DOE Headquarters approval. Once the cleaning of WM-180 is complete, a Tier 2 closure plan will be prepared and approved to discuss the readiness to proceed with final closure (grouting) activities.

## 5.2 Comprehensive Environmental Response, Compensation, and Liability Act Requirements

In November 1989, the INEEL was listed on the National Priorities List (54 Federal Register [FR] 223, 1989). In 1991, the FFA/CO was written to establish a framework for fulfilling both CERCLA remedial action and RCRA corrective action requirements (DOE-ID 1991). The FFA/CO divides the INEEL into 10 waste area groups, which are further divided into OUs. INTEC is designated as Waste Area Group 3 with 14 OUs (DOE-ID 1991).

For closure of tank systems, HWMA/RCRA requires investigation of associated contaminated soils. Past leaks from TFF transfer piping have contaminated areas of the TFF soils. The OU 3-13 final ROD (DOE-ID 1999) states that investigation of the hazardous constituents in the TFF soils will be addressed during the OU 3-14 RI/FS (DOE-ID 2003c). Therefore, remediation of these soils will be addressed by the CERCLA OU 3-14 ROD and will address the RCRA closure requirements within the regulatory framework and authority of the FFA/CO as a RCRA corrective action. Table 4 identifies constituents of concern that are reasonably expected in the soils. A summary of information regarding TFF soils from investigation/remediation activities available at the time of final TFF closure will be included in the PE certification documentation.

## 5.3 High-Level Waste and Facilities Disposition Environmental Impact Statement Requirements

Closure of the TFF and Tank WM-180 also may be affected by the decisions made on the basis of the *Idaho High-Level Waste and Facilities Disposition Final Environmental Impact Statement* (DOE 2002). This document addresses three primary decision-making goals:

- How to treat sodium-bearing waste
- How to treat HLW calcine into final waste form ready to leave the State of Idaho by December 2035
- How to conduct the disposition of associated HLW program facilities, including the TFF.

The three environmental impact statement general closure alternatives are

- Clean closure
- Closure to landfill standards
- Performance-based closure.

The environmental impact statement was prepared to fulfill commitments DOE made as part of the terms of a 1995 settlement agreement and court order with the State of Idaho (State of Idaho, DOE, and Department of the Navy 1995). Under the agreement and court order, DOE must cease use of the TFF tanks by 2012 and treat all HLW currently at the INEEL so that the waste is ready for removal from the State of Idaho by 2035. To meet this requirement, DOE must issue a ROD no later than December 31, 2009, based on an environmental impact statement that analyzes alternatives for treating INEEL HLW. On September 19, 1997, DOE issued a "Notice of Intent to Prepare a High-Level Waste and Facilities Disposition Environmental Impact Statement, Idaho Falls, Idaho" (62 FR 182, 1997). The environmental impact statement was issued in September 2002 (DOE 2002).

Both DOE and the State of Idaho have designated a performance-based closure method as the preferred alternative for disposition of HLW facilities at INTEC. These methods encompass three of the six facility disposition alternatives analyzed in the environmental impact statement: clean closure, performance-based closure, and closure to landfill standards. These methods are consistent with the closure approach proposed for the TFF in this closure document. A DOE ROD is expected in 2004 or early 2005.

## **6. CLOSURE-GENERATED WASTE HANDLING AND DISPOSAL**

In accordance with IDAPA 58.01.05.006 (2004) (40 CFR 262.11 [2002]), all solid waste generated during the closure process for Tank WM-180 is required to be properly characterized to determine if the waste is a hazardous waste. If so, the waste must be managed as a hazardous waste in accordance with all applicable HWMA/RCRA regulations and hazardous waste determination. Circumstances may arise during closure implementation that requires removal of equipment and treatment for reuse or disposal rather than leaving the equipment in place as planned. Conversely, leaving some equipment in place may be necessary or desirable to limit personnel radiation exposure.

As stated in more detail in Section 1.2, wastes stored in Tank WM-180 exhibit the hazardous characteristics of corrosivity (HWN D002) and the characteristic of toxicity for lead (D008), mercury (D009), cadmium (D006), and chromium (D007). Also associated with the waste are four RCRA listed waste codes: F001, F002, F005, and U134 (Gilbert and Venneman 1999).

### **6.1 Decontamination and Treatment of Equipment for Disposal**

Contaminated equipment from Tank WM-180 closure activities will be decontaminated or treated for all hazardous constituents present. The presence of hazardous constituents will be indicated by the baseline sampling results and the historical inventory of wastes managed in the tanks. Treatment will consist of subjecting the equipment to one or more existing treatment technologies identified in IDAPA 58.01.05.011 (2004) (40 CFR 268.45, 2004). The specific technology or technologies will be selected at the time of closure based on the contaminants subject to treatment, the effectiveness of the selected technology, and the ability of equipment to be effective in a highly radioactive environment. Equipment to be disposed of as solid waste will be disposed of in accordance with applicable local, state, and federal requirements. In some cases, the contaminated equipment may be dismantled, packaged, and transported to an onsite or offsite treatment, storage, and disposal facility. Section 6.3 describes available storage, treatment, and disposal options. Hazardous waste determinations will be performed on waste in accordance with 40 CFR 262.11 (2002).

### **6.2 Equipment and Structures to be Reused**

The following equipment and structures are designated for potential reuse and will be decontaminated or disposed of if they become contaminated during WM-180 closure activities:

- Tank Closure Equipment—Grout delivery equipment, wash ball, heel sampling equipment, video equipment, and tank lighting
- Trucks—Utility, flat-bed, and dump
- Cranes, backhoes, front-end loaders, and excavator
- Temporary Vessel Off-Gas System—Blower, filter skids, condensate accumulation receiver tank, and ducting
- Decontamination equipment (line spray washing systems)
- Grout System—Pump and piping
- Radiological Protection Equipment—Shielding and large area containment tents

- Buildings—Temporary enclosure and construction trailers
- Miscellaneous—Pipe-cutting tools, liquid catches, buckets, and brushes.
- Utilities—Electrical power (protective devices, conductors, and distribution systems), water (pressure regulators, control valves, and distribution/delivery systems), steam, and/or air distribution systems, as deemed appropriate
- Direct-heel sampling pump or simple sampler.

All equipment and structures that have documented contamination, visible signs of contamination, or known contact with waste materials will be decontaminated. Also, the contaminated equipment may be dismantled, packaged, and transported to an onsite storage/treatment facility for decontamination before reuse (see Section 6.3). For example, grout system piping may require decontamination in the INTEC debris treatment facilities before reuse.

### 6.3 Closure-Generated Waste

INTEC storage and treatment systems (e.g., PEWE and TFF) may be used to store and treat wastes generated from the following sources:

- Vaults, vault sumps, and liquid removal lines to tanks and to the PEWE
- Condenser pit covers, pits, vessel off-gas lines, and vessel off-gas drain lines
- Purge liquids and decontamination solutions.

Alternatives for treatment and disposal methods for the liquid sodium-bearing and calcined wastes are addressed in the *Idaho High-Level Waste and Facility Disposition Final Environmental Impact Statement* (DOE 2002). If necessary, decontamination materials and residues (e.g., personal protective equipment, sampling equipment, and HEPA filters) will be placed in containers labeled with the date of accumulation and a barcode identifier, sampled and analyzed, and held within the TFF as mixed, low-level, or transuranic waste. Based on process knowledge and the results of analysis, closure waste will be managed to ensure proper handling, treatment, storage, and disposal. Examples include, but are not limited or restricted to, the following:

- The HEPA filters determined to be waste or debris may be transferred to CPP-659 New Waste Calcining Facility HEPA filter storage before treatment in the CPP-659 New Waste Calcining Facility HEPA Filter Leach System. These HEPA filters will be disposed of either on-Site at the Radioactive Waste Management Complex or off-Site. Filter leaching will be necessary before disposal at the Radioactive Waste Management Complex.
- Hazardous or mixed waste may be accumulated within the area of closure and either sent off-Site for treatment and disposal or sent to CPP-1619, the Hazardous Chemical and Radioactive Waste Storage Facility, before shipment off-Site. If hazardous waste generated from the closure activity is maintained within the boundaries of Tank WM-180 closure, the 90-day storage limit will not apply; all other handling, packaging, and inspection rules will apply to protect human health and the environment. The HWMA/RCRA facility closure requirements specify that the boundaries applicable to cleanup of closed facilities are the unit boundaries of the unit being closed. The boundaries for DOE HLW facility closures are based on the performance assessment conducted during closure activities (DOE-ID 2003d).

If applicable, fluids from decontamination may be contained within a work/closure area or collected in containers until characterization results are obtained to ensure compliant storage and/or treatment and disposal.

## **6.4 Management of Excavated Soils**

Management of soils excavated during TFF closure activities will be conducted consistent with the approved methods outlined in the INTEC C40 valve box soil work plan (INEEL 2000b). Soil excavated during TFF closure activities either will be returned to the excavation or managed in accordance with applicable HWMA requirements within the 24-month timeframe. The TFF closure actions, which may include soil excavation, are expected to require a typical construction season, but may be delayed by unexpected circumstances. The project may require excavation of about 20 yd<sup>3</sup> of soil. Soil excavated during TFF closure activities will be used as backfill for this project only.

### **6.4.1 Excavation**

One or more construction piles will be established immediately adjacent to the excavation where excavated soil will be held temporarily before transfer to a staging pile. Transfer will be accomplished using TFF-approved equipment (e.g., backhoe, front-end loader, hand shovels, vacuum, and excavator). These temporary construction piles are separate from the soil staging piles. Soil from the construction piles will be removed (down to approximately the last 6 in.) at the end of each day and then covered to prevent the spread of loose soil.

### **6.4.2 Staging**

Staging piles, as used for this project, will provide for temporary staging of soil (no longer than 24 months) before reuse as a backfill for the TFF closure project or placement into containers for long-term management. Using staging piles will provide a reliable, effective, and protective option for staging soil before use as backfill. Soil contaminated at levels above 50 mrem/hr (on or near contact) will not be put directly into staging piles but will be placed into containers (probably metal boxes or industrial-duty sacks or bags) to prevent possible spread of radiological contamination. Each container will be marked to indicate the location and depth at which the soil originated. This soil also will be placed back into the excavation near the depth and location of origination. Information on the location, depth, and level will be provided to the CERCLA program for resolution at final closure.

The staging piles will be placed on a double layer of an impermeable liner to prevent contamination of underlying soil or asphalt. The piles will be covered with impermeable material to prevent windblown spread of radionuclides and hazardous constituents. The covers also will prevent intrusion and percolation of precipitation through the soil. The covers will be secured to the liner and to each other using standard methods such as timbers and sandbags. Netting will be placed over the covers to aid in preventing wind damage. Precipitation run-off from the covers will be diverted away from the piles and then away from the TFF area through the existing storm water diversion system. The same diversion system will prevent precipitation run-on. The covers will be lifted or removed to allow working access to the staging pile as required. The staging pile will be re-covered and the cover secured at the end of each day.

Soil potentially contaminated with hazardous waste that has been placed into containers will not be staged in a HWMA/RCRA-regulated treatment, storage, or disposal facility such as CPP-1617. The containers will be managed within the area of contamination as if they are in a less-than-90-day storage area until the soil is returned to the excavation as backfill. Excess soil, if any, will be managed in accordance with a formal hazardous waste determination and any applicable no-longer-contained-in

determination. For the purpose of the TFF closure project, soil placed into containers for radiological control will be deemed no different than soil placed into staging piles; land disposal restriction requirements will not be violated.

#### **6.4.3 Soil Emplacement as Backfill**

Soil will be used as backfill in a way that does not significantly increase potential exposure at the TFF either through direct exposure to radiation or by migration of contaminants. Soil will generally be placed back into the excavation in reverse order of removal (i.e., last out, first in). Soil emplacement in the excavation will be completed such that the site profile/condition before and after the project is consistent.

#### **6.4.4 Soil Tracking**

A single one-time-only waste stream will be established for tracking the management of the soil associated with closure of each TFF tank. The INEEL Integrated Waste Tracking System material profile will track excess soil placed into containers for long-term management. For soil used as backfill, only the volume will be tracked via the INEEL Integrated Waste Tracking System under a single-container profile tied back to the waste stream.

Several steps will be used to track soil during excavation, staging, and backfill activities. Radiological control personnel will complete necessary surveys during all soil movement.

Log sheets will be completed during initial excavation and when soil is used as backfill. These forms allow tracking of soil from the excavation to a staging pile; from the staging pile to backfill; into containers for radiological control; and use of containerized soil as backfill. The log sheets also provide a means to initially identify containers used for long-term storage of excess soil. These log sheets will be retained as part of the operating record.

## **7. MAXIMUM EXTENT OF THE OPERATION UNCLOSED**

Closure of Tank WM-180 and the final closure of the TFF represent a partial closure of the INEEL facility. Final closure of the remaining HWMA/RCRA-regulated operational units at the INEEL will be conducted in accordance with applicable interim status or approved HWMA/RCRA Part B closure plans. In accordance with the information required under IDAPA 58.01.05.009 (2004) [40 CFR 265.112(b)(2), 2004], “the maximum extent of the operation which will be unclosed during the active life of the facility” must be identified. Therefore, an estimate of the maximum extent of operations that will remain unclosed (open) at the INEEL after closure of Tank WM-180 is to be determined. An estimate of the maximum extent of operations that will remain unclosed on the entire INEEL facility is available in the *HWMA/RCRA Part A Permit Application for the Idaho National Engineering and Environmental Laboratory* (DOE-ID 2003e) and other approved HWMA/RCRA Part B permits for the INEEL.

## 8. TIME ALLOWED FOR CLOSURE/EXTENSION

IDAPA 58.01.05.009 (2004) (40 CFR 265.113, 2004) requires that closure of the TFF must commence within 90 days after receiving the final volume of hazardous wastes or within 90 days after approval of the closure plan, whichever is later. The regulations allow DEQ to approve a longer period to commence closure, provided

- “The activities required to comply with this paragraph will, of necessity, take longer than 90 days to complete”
- The operator “has taken and will continue to take all steps to prevent threats to human health and the environment, including compliance with all applicable interim status requirements.”

The second modification to the Consent Order (IDHW 1998) specifies that DOE must cease use of Tanks WM-182 through WM-186 by June 30, 2003, and the remaining tanks by December 31, 2012.<sup>c</sup> Ceasing use of the tanks means that DOE must empty the tanks to their heels, that is, the liquid level remaining in each tank must be lowered to the greatest extent possible by the use of existing transfer equipment. As described in Section 1, closure of the TFF will be conducted in phases, with partial closures of groups of tanks leading to final closure of the TFF. IDAPA 58.01.05.009 and 40 CFR 265.113 also require that closure activities be completed in accordance with the approved closure plan “within 180 days after receiving the final volume of hazardous wastes” or “within 180 days after approval of the closure plan, if that is later.” The director of DEQ may approve an extension to the closure period provided it is demonstrated that

- “The activities required to comply with this paragraph will, of necessity, take longer than 180 days to complete”
- The operator “has taken and will continue to take all steps to prevent threats to human health and the environment from the unclosed but not operating hazardous waste management unit or facility, including compliance with all applicable interim status requirements.”

Closure activities for the TFF tanks are anticipated to take longer than 180 days to complete for the following reasons:

- The highly radioactive wastes stored in the tanks will require much of the sampling and waste removal work to be performed using remote handling technology, which will require significant lead times to set up and conduct
- The approach for partial closure of the TFF tanks in sequence will require the continued availability of storage space in other tanks and treatment capacity in the INTEC waste treatment systems for the wastes generated; operational timeframes in these systems do not allow closure within 180 days
- Closure to performance-based standards will involve an iterative process of decontamination, sampling, analysis, data review, and possibly, additional decontamination.

---

c. The Consent Order allows Tank WM-185 to be used as an emergency spare tank.

For these reasons, the closure of each set of tanks in the TFF is likely to require much longer than 180 days. Current planning estimates suggest each partial closure phase will require several years. An extension to the 180-day period for Tank WM-180 is requested to 667 days.

Quarterly reports will be provided for the closure of Tank WM-180. These reports will be integrated with the quarterly reports for (1) WM-182 and WM-183; (2) WM-184, WM-185, and WM-186; and (3) WM-103, WM-104, WM-105, and WM-181. The reports will be provided to DEQ within 30 days of the end of each quarter of the fiscal year. The reports will identify the status of the closure activities, identify the status of the entire closure schedule, and outline any issues or concerns relative to the milestone of completing partial closure. Reporting will begin at the end of the first quarter after approval of the closure plan. The reports will be submitted no later than January 31, April 30, July 31, and October 31 of each year (the same schedule as for WM-182 and WM-183), and will continue until closure is complete. Table 6 lists the durations and descriptions of the planned activities for closure of Tank WM-180.

Finally, IDAPA 58 and 40 CFR 265.112(a) (2004) require that by May 19, 1981, or by six months after the effective date of the rule that first subjects a facility to provisions of this section, the owner or operator of a hazardous waste management facility must have a written closure plan. This closure plan is being submitted in accordance with the Consent Order, which requires submittal of the first closure plan on or before December 31, 2000, as described in the second modification to the Consent Order (IDHW 1998).

The integration of HWMA/RCRA closure and DOE closure is vital to the success of the TFF closure. Implementation of the DOE closure plan by DOE must be coordinated with the implementation of the HWMA/RCRA closure plan by DEQ. Both a DOE Authorization to Proceed and State of Idaho approval must be obtained before any irreversible closure actions may begin. Preliminary tank washing may commence before these closure plans are approved.

Table 6. Durations and descriptions of planned activities scheduled for WM-180 closure.<sup>a</sup>

Duration	Description
0 day	Receive approval of partial closure plan and receive DOE Authorization to Proceed <sup>b</sup>
328 days	Remove waste and decontaminate Tank WM-180
339 days	Evaluate results, grout, and close
60 days	Submit PE supporting documentation (this time is in addition to the 667 days for closure)

a. The sequence of tank closure may change based on timing and logistics.

b. Waste removal, decontamination, and evaluation will commence on or before approval of the partial closure plan. Grouting will commence after the DOE Authorization to Proceed is received.

## **9. CLOSURE PLAN MAINTENANCE AND AMENDMENTS**

In accordance with IDAPA 58.01.05.009 (2004) [40 CFR 265.112(a), 2004], a copy of the most current version of the closure plan will be maintained by the facility until closure is certified. The plan will be furnished to the DEQ director, upon request, any time before closure certification. This closure plan will be modified, as necessary, in accordance with IDAPA 58.01.05.009 [40 CFR 265.112(c)] and as follows:

- Whenever changes in operating plans or facility design significantly affect the closure plan
- If there is a change in the expected year of closure
- If, in conducting closure activities, unexpected events require a modification
- If a change in state or federal laws or regulations requires a change in the closure plan
- If the regulatory authority requests modification of the closure plan in accordance with IDAPA 58.01.05.009 [40 CFR 265.112(c)(4)]
- At the time of closure to address the schedule for closure, changes to regulatory standards for cleanup, biased sampling based on the operating record, specific decontamination methods/technologies to be employed, changes to how and where disposal of equipment and structures will take place, and other changes necessary to accomplish the “clean closure” performance standard.

Written notifications or requests for amendment or modification of this closure plan will be submitted, along with a copy of the amended plan, to DEQ or DEQ will be otherwise notified:

- 60 days before a proposed change in operating plans or design of the waste management unit or facility
- No later than 60 days after an unexpected event occurs that affects the closure plan
- No later than 30 days after an unexpected event occurs during closure (IDAPA 58.01.05.009 [40 CFR 265.112(c)]).

## 10. CERTIFICATION OF CLOSURE

Certification of closure will be provided by an independent Idaho-registered PE and the facility contractor and/or DOE Idaho Operations Office, in accordance with IDAPA 58.01.05.009 (2004) (40 CFR 265.115, 2004), at final closure of the TFF system. Certification of partial closures is not required (EPA 1998). The TFF tanks will not be certified closed until all of the tanks have been decontaminated and the waste removed.

Within 60 days of completion of final closure covered by this plan, the owner or operator must submit to the DEQ director, by registered mail, a certification that the hazardous waste management unit has been closed in accordance with the specifications in the approved closure plan. The certification will be signed by the owner or operator and by the PE. Documentation supporting the PE's certification must and will be furnished to the DEQ director. These actions will meet the certification of closure requirements stated in 40 CFR 265.115. The PE certification information will be submitted to DEQ 60 days after completion of this closure plan for Tank WM-180. Records of each partial closure certification will be stored at the INEEL for certification upon final closure.

As data are collected in the partial closures of the TFF, the data will be combined using the statistical methods shown in Appendix D. Final closure conditions for the TFF will be determined when the data from all of the tanks and ancillary equipment are compared to the TFF ALs. The 95% upper confidence level of the mean of all samples will be compared to the ALs. Tank and ancillary equipment sample populations may be considerably different; therefore, two or more upper confidence level calculations may be performed and compared to ALs.

If closure of the TFF systems to the landfill closure standard is necessary, a "Notice in Deed" and survey plat will be submitted to the Butte County Courthouse in accordance with IDAPA 58.01.05.009 (2004) (40 CFR 265.119, 2004), and the tanks will be closed in accordance with the contingent landfill closure plan (DOE-ID 2003a). The survey plat will be prepared and certified by an Idaho professional land surveyor and will indicate the location and dimensions of the tank system that requires closure to the landfill standard. The "Notice in Deed" will state the following:

- The land has been used to manage hazardous waste
- Land use is restricted under IDAPA 58.01.05.009 (40 CFR 265.119)
- The facility contractor and/or DOE Idaho Operations Office have an obligatory commitment to restrict disturbance of the closed landfill unit.

In addition, a record describing the type, location, and quantity of hazardous waste disposed of in any and all WM-180 tank system components will be submitted to DEQ and the Butte County Commissioners (IDAPA 58.01.05.009 [40 CFR 265.119]).

The PE certification information will document all closure activities so there is adequate information provided for each phase of closure. Closure activities for Tank WM-180 under this closure plan will be considered complete upon submittal of the supporting documentation from the independent PE to DEQ.

## **11. COST, FINANCIAL ASSURANCE, AND LIABILITY REQUIREMENTS**

The INEEL is owned and operated by the U.S. Government. Therefore, the facility is, in accordance with IDAPA 58.01.05.009 (2004) [40 CFR 265.140(c), 2004], exempt from the financial requirements of IDAPA 58.01.05.009 (40 CFR Part 265, Subpart H).

**Appendix A**  
**Detailed INTEC Facility Description**

## **Appendix A**

### **Detailed INTEC Facility Description**

This appendix provides a detailed description of the INTEC TFF to further support the closure plan. The facilities within the TFF and associated equipment and processes are described.

#### **A-1. INTEC AND TANK FARM FACILITY DESCRIPTION**

INTEC, formerly known as the Idaho Chemical Processing Plant, is located in the south-central portion of the INEEL. INTEC began operations in 1953 and was historically a fuel reprocessing facility for defense projects, research, and storage of spent nuclear fuel. The high-level radioactive liquid wastes generated from fuel reprocessing operations were stored in stainless steel storage tanks contained in concrete vaults at the TFF.

In 1992, DOE decided to end the fuel reprocessing mission at INTEC. This decision led to the phase out of fuel dissolution, solvent extraction, product denitration, and other processes. The current mission of INTEC is to receive and store spent nuclear fuels and radioactive wastes, treat and convert wastes, and develop new technologies for waste and waste management for DOE. Employees are to do this in a cost-effective manner that protects the safety of INEEL employees, the public, and the environment.

The INTEC facility is situated on approximately 200 acres (80 ha) that lie within a perimeter fence. Located outside the INTEC perimeter fence are parking areas, a helicopter landing pad, the waste water treatment lagoon, various pits and percolation ponds, and the Tank Farm Project Support Facility. These areas occupy approximately 55 acres (22 ha).

#### **A-2. TFF TANK CONTENTS AND CONSTRUCTION INFORMATION**

The TFF comprises

- Nine 300,000-gal and two 318,000-gal active stainless steel tanks (hereafter referred to as 300,000-gal tanks), each of which is contained within a concrete vault
- Four inactive 30,000-gal stainless steel tanks
- Valve boxes, encasements, and various process and instrumentation piping associated with the tanks (INEEL 2000).

The physical layout of INTEC and the TFF is depicted in Figure A-1. A conceptual view of the TFF is depicted in Figure A-2.

##### **A-2.1 300,000-gal Tanks**

The 300,000-gal storage tanks, WM-180 through WM-190, are contained in belowground, unlined, octagonal (WM-180 through WM-186) or square (WM-187 through WM-190) concrete vaults. A diagram of Tank WM-182 is shown in Figure A-3 as an example of the construction and design of the tanks. The tanks are stand alone, stainless steel, cylindrically shaped vessels. Each tank is

Figure A-1. Location of the TFF at INTEC.

Figure A-2. Conceptual overview of the TFF.

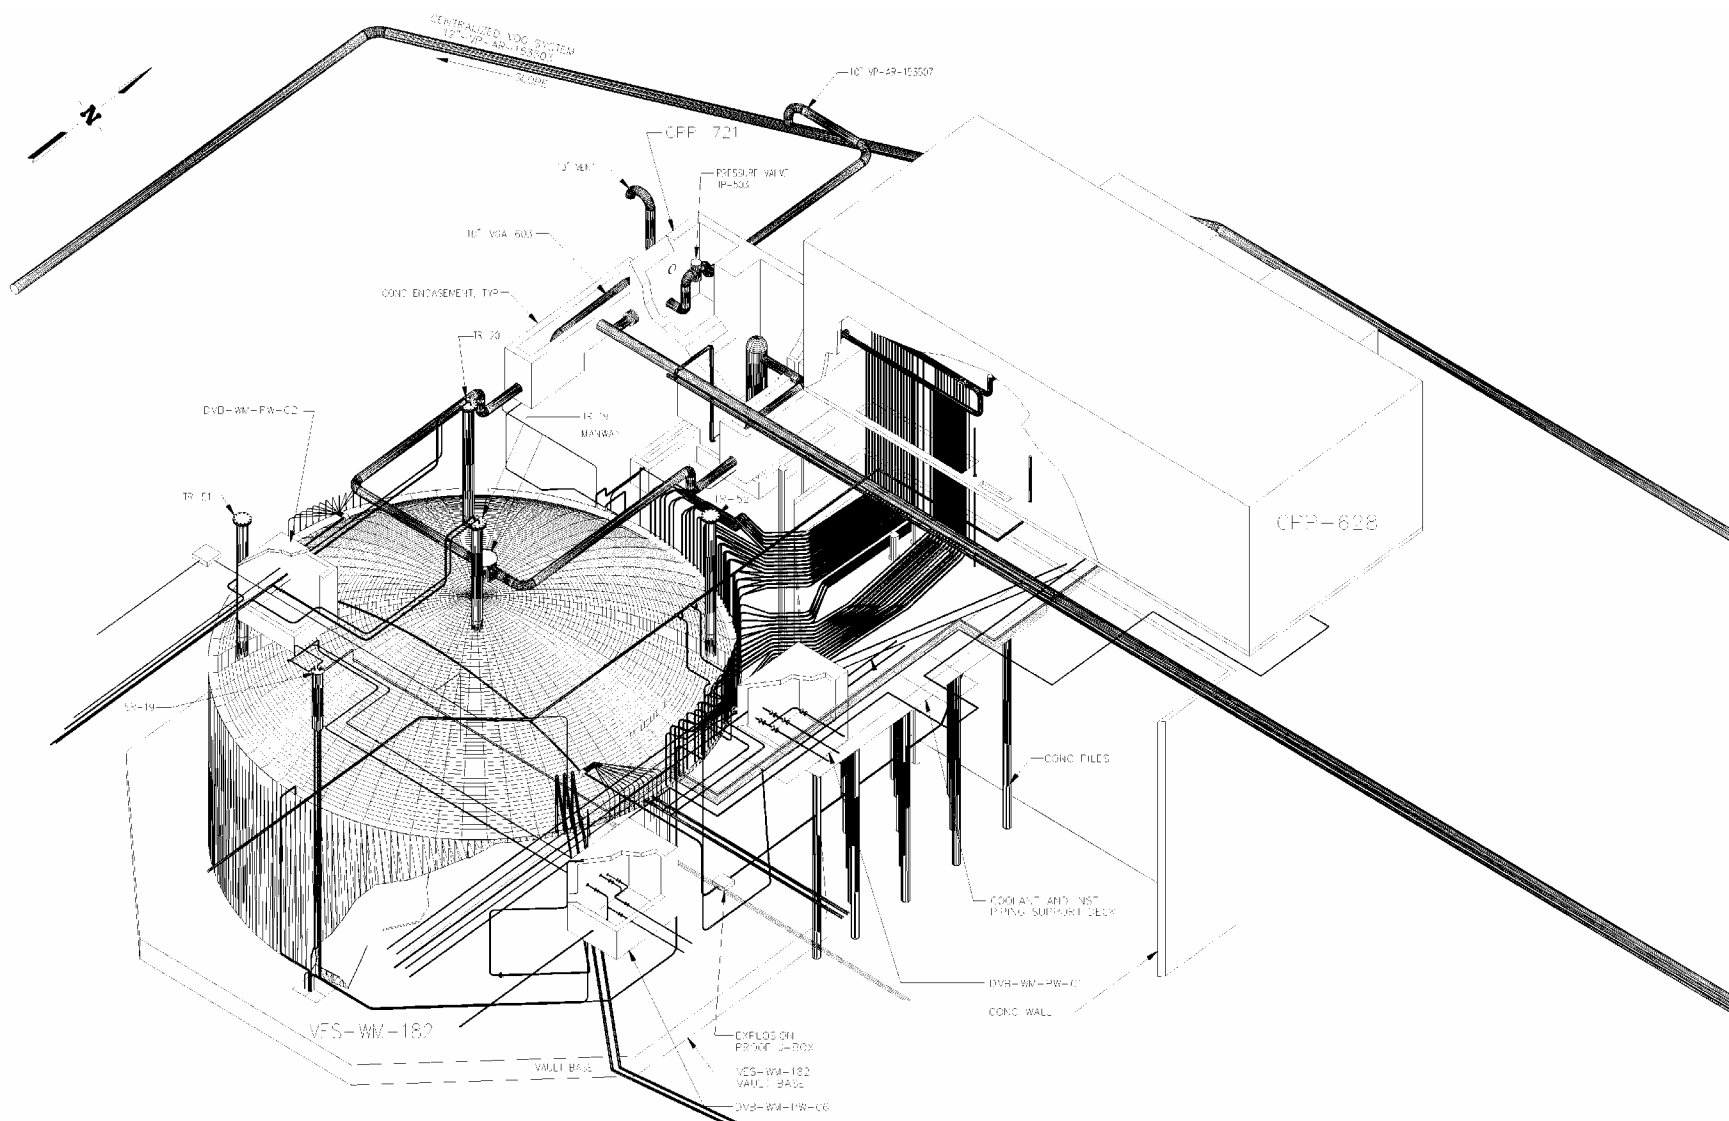

Figure A-3. Cutaway view of Tank WM-182.

administratively limited to storing 285,000 gal of liquid waste. The inside tank diameter and wall height are 50 ft (15 m) and 21 ft (16.4 m), respectively, with the exception of the 23-ft (7.0-m) high walls for Tanks WM-180 and WM-181. The higher walls for these two tanks provide a storage capacity of 318,000 gal for each tank.

Tanks WM-182 through WM-190 are constructed with an 11-in. (28-cm) wide horizontal plate (WM-180 and WM-181 have a 4-in. [10-cm] plate) that connects the top of the tank wall to the dome. This horizontal plate provides a flat surface for process and instrumentation pipelines to penetrate the tank. Equally spaced gussets support the plate from underneath. Tank domes are spherical in shape and rise above the tank wall from 8.5 to 8.7 ft (2.6 to 2.7 m).

Eight of the 11 tanks contain stainless steel cooling coils (all except WM-181, -184, and -186). The cooling coils maintain the liquid waste temperature below 95°F (35°C) for fluoride-containing waste. The liquid waste is maintained below these temperatures to minimize tank corrosion. The lower tank temperature also reduces the liquid surface evaporation rate. Demineralized water in the cooling coils, along with chromate additives, circulates through a closed system and is cooled by secondary cooling water.

Access to the 300,000-gal tanks is provided through risers. Each tank has four to five 12-in. diameter risers. Tanks WM-184 through WM-190 also have 18-in. (46-cm) diameter risers (Tanks WM-184 through WM-188 have one 18-in. riser, WM-189 and WM-190 have two 18-in. risers). Most risers have equipment installed in them, such as radio frequency probes for level measurement, corrosion coupons, or waste transfer equipment (steam jets and airlifts). Two steam jets are located inside each tank, with the exception of WM-189 and WM-190; these two tanks have one steam jet and one airlift pump. A single steam jet can transfer waste out of a tank at approximately 50 gal/min. An airlift can transfer waste out of a tank at approximately 35 gal/min. Table A-1 provides general construction information on the 300,000-gal tanks.

## **A-2.2 30,000-gal Tanks**

The four inactive 30,000-gal tanks are stainless steel belowground tanks on reinforced concrete pads. The tanks have a diameter of about 11.5 ft, are 38 ft long, and are covered by compacted gravel. Tanks WM-103, -104, -105, and -106 were buried at depths of 28.5, 29.0, 29.5, and 29.5 ft (8.69, 8.84, 8.99, and 8.99 m), respectively. Like the 300,000-gal tanks, the 30,000-gal tanks do not have secondary containment that can be certified to meet HWMA (State of Idaho 1983)/RCRA (42 USC 6901 et seq., 1976) requirements. Unlike the 300,000-gal tanks, the 30,000-gal tanks do not have vaults.

The tanks rest on concrete slabs that are 47.5 ft long by 17 ft wide by 1.25 ft (14.5 by 5.2 by 0.381 m) thick. These slabs were constructed with a 0.75 by 1-ft (0.23 by 0.3-m) high curb surrounding the slab perimeter to contain leaking waste. A gravel pad was placed inside the curb. Sumps, 2 by 2 by 2-ft (0.6 by 0.6 by 0.6-m) deep were cast into the northeast corner of each concrete slab.

Each tank has a total volume of 30,750 gal (116,400 L). The tanks are horizontal cylinders with American Society of Mechanical Engineers (ASME) dished heads attached on both ends. Generalized information and tank dimensions can be found in Table A-2.

Underground pillars anchored to bedrock support the concrete pipe encasements associated with the 30,000-gal tanks. The base slabs, which the tanks rest on, sit on undisturbed soil.

All four tanks contain stainless steel, closed loop, recirculating cooling coils to control liquid waste temperature, evaporation rate, and condensation accumulation. Base slab sump access is provided by a

2-ft (0.6-m) diameter concrete riser that extends to grade level. A permanently installed sump jet pump obstructs the sump access riser interior.

Access to the 30,000-gal tanks is provided by three 6-in. and one 3-in. diameter risers that reach to grade level. Tank jets are connected through the tank personnel access and extend underground to the other TFF locations. Tanks WM-103 and WM-104 are installed with four steam jets, while Tanks WM-105 and WM-106 are installed with two steam jets for liquid removal.

## **A-2.3 Vaults**

The vault floors are approximately 45 ft (14 m) belowground. The vaults containing the tanks are of three basic designs: monolithic octagonal, pillar and panel octagonal, or monolithic square. The vault roofs are covered with approximately 10 ft (3 m) of soil to provide radiation shielding. The vault roofs are 6-in. (20-cm) thick concrete. Details of the various vaults are provided in Table A-3.

### **A-2.3.1 Monolithic Octagonal Vaults**

The two oldest tanks at the TFF, WM-180 and WM-181, were constructed from 1950 to 1952 and are contained in poured-in-place monolithic octagonal concrete vaults. These are the only vaults that have been qualified through analytical modeling to meet seismic criteria. The vault floors are octagonal and were poured on bedrock. They are flat with sump areas cast within the vault floor for liquid drainage. Vault CPP-180 (Tank WM-180) was installed with two sump areas: 2 by 2 by 4 ft (0.6 by 0.6 by 1 m) deep in the southeast corner and 2.5 by 2.5 by 2 ft (0.76 by 0.76 by 0.6 m) deep in the northeast corner. Vault CPP-781 (Tank WM-181) was installed with one sump area 2 by 2 by 4 ft (0.6 by 0.6 by 1 m) deep in the southwest corner. The concrete vault walls were cast once the vault floors were poured. The concrete vault roof was cast in place. The vault roof was constructed to rise at an angle from the vault walls and flatten toward the middle.

### **A-2.3.2 Pillar and Panel Octagonal Vaults**

The five tanks contained in vaults of pillar and panel octagonal construction, Tanks WM-182 through WM-186, were constructed from 1954 to 1957. Also in octagonal vaults, the tanks contained in the pillar and panel vaults are of prefabricated construction and, therefore, are not considered as robust as the tanks contained in monolithic vaults (Palmer et al. 1998). The pillar and panel vaults were not analyzed for and probably would not qualify for Performance Category (PC)-4 seismic criteria.<sup>a</sup> A diagram of the pillar and panel vault design is presented in Figure A-4. The octagonal concrete floors were poured on bedrock. Each floor has a 4-in. (10-cm) slope, beginning at the floor center and tapering to the curb. This slope creates a conical shaped floor. Sump areas 1 by 1 by 1 ft (0.3 by 0.3 by 0.3 m) deep located on the north and south side of each vault were cast within the vault floor. There is a 6 by 6-in. (20 by 20-cm) curb cast 6 ft (2 m) in from the concrete base slab. The curb encloses an octagonal area 51 ft (16 m) wide, encircling a sand pad.

The vault walls are constructed of concrete pillars and panels. The roofs are constructed of similar materials.

### A-2.3.3 Monolithic Square Vaults

The four tanks contained in reinforced, poured-in-place, monolithic square, four-sectioned (“four pack”) concrete vaults, Tanks WM-187 through WM-190, were constructed from 1958 to 1964. The vaults of these tanks are believed to meet PC-4 criteria, but the analysis for qualification was not performed (Palmer et al. 1998).<sup>b</sup> The square concrete vault floors were poured side by side on bedrock. The floors are constructed with a 4-in. (10-cm) slope, beginning at the floor center and tapering to the curb. The slope creates a conical-shaped floor similar to the pillar and panel vaults. Two sump areas, 12 by 12 by 12 in. (30 by 30 by 30 cm), are cast within the vault floors of WM-187 and WM-188. WM-189 and WM-190 have three sumps with two (hot sumps) measuring 12 by 12 by 36 in. (30 by 30 by 90 cm) and one (cold sump) measuring 3 by 5 by 9 ft (0.9 by 1.5 by 2.3 m) deep. The sumps are located in the northwest and southeast corners for the WM-187 and WM-189 vaults, and the northeast and southwest corners for the WM-188 and WM-190 vaults. A 6 by 6-in. (20 by 20-cm) octagonal curb was installed inside the square vault. The curb creates an octagonal area 51 ft (16 m) wide, encircling a sand pad.

## **A-2.4 Transfer Equipment**

Waste transfer, cooling, decontamination, instrumentation, and vessel off-gas pipelines are plumbed to individual tanks and vaults. The waste transfer pipe running from the valve boxes to just outside the vault walls is encased in concrete enclosures with stainless steel liners to prevent radioactive waste from escaping. The concrete enclosures do not penetrate the vault. Pipes penetrate the vault via a pipe-in-pipe sleeve. Drains in each concrete encasement allow liquid from a leaking pipe or water infiltration to flow back to the nearest tank vault. Steam-powered sump jets are installed in the sumps on the north and south sides of each tank. The sump jets transfer liquid from the vaults to the respective tanks.

Jet pumps are installed to remove liquid from the tanks. These jet pumps are located 3 to 9.5 in. (8 to 24 cm) above the tank floor. Permanent steam lines are connected to each jet pump and routed through underground piping to steam sources within the TFF Control House (CPP-628). A double-contained process waste is routed underground from the jet pumps to the main transfer/filling system.

All primary waste lines that transport waste within the TFF are buried and enclosed in pipe encasements known as secondary containment. The four main types of TFF secondary containment initially used are

1. Split tile (ceramic cast pipe with concrete joints)
2. Stainless steel-lined concrete troughs
3. Direct-buried pipes in concrete
4. Double-walled stainless steel pipe.

During recent TFF upgrades, most pipe sections encased in ceramic tile were replaced or abandoned in place. Short sections of ceramic pipe still remain on the active line list that serves Tanks WM-180 and WM-181. These lines cannot be used unless authorized by upper management.

Any fluid leaking from a process line drains into an encasement and then into a valve box or vault sump. Leaking fluid is detected by radiation and/or level detection instrumentation. A leaking line is immediately taken out of service and is not reused until it has been repaired. Waste collected in the valve box or vault sumps is jetted to Tank WL-133 or drained to Valve Box C12. Wastes collected in Valve Box C12 also are jetted to WL-133. All wastes are then transferred to the PEWE for processing.

### **A-2.4.1 30,000-gal Tank Liquid Transfer Equipment**

Permanent sump jet pumps are installed in each of the four sumps associated with these tanks. Liquid removal jet pumps are installed in each tank, with lines penetrating through the tank personnel access. The inlets to these tanks are currently disconnected but the outlets are still tied to the TFF piping system.

### **A-2.4.2 C-Series Valve Boxes**

Valve boxes, located where pipe runs change directions, were constructed to provide protection for pipe joints, improve valve access, increase protection to workers from contaminated soils, and reduce valve repair costs by minimizing ground excavation. Valve boxes were installed with sumps and attached

drain lines to transfer liquid waste to vault sumps or the PEWE in the event pipe encasement drains or process valve leaking occurs.

Each concrete valve box is reinforced and lined with stainless steel. Bitumastic #50, a material similar to tar thatch, was used as filler around pipe sleeves or on carbon steel piping. The approximate valve box dimensions are 6 ft long by 6 ft wide by 6.5 ft (2 by 2 by 2.0 m) high with a wall thickness of 6 in. (20 cm). Typically, valve boxes extend approximately 1 ft (0.3 m) aboveground.

#### **A-2.4.3 Process Waste Pipelines**

During recent TFF upgrades, most pipe sections encased in split tile either were replaced or abandoned in place (footnote a, page A-2). Process waste lines and respective secondary containment are generally covered with 10 to 15 ft (3 to 4.6 m) of soil.

Any fluid leaking from a process line drains into an encasement and then into a valve box or vault sump. Leaking liquid is detected by radiation and level detection instrumentation. Waste collected in a valve box or vault sump is jetted to Tank WL-133 (located in Building CPP-604) or drained to Valve Box C12. Waste collected in Valve Box C12 also is jetted to Tank WL-133. Waste from Tank WL-133 is sent to the PEWE for processing.

## **Appendix B**

### **Development of Action Levels for the HWMA/RCRA Closure of Tank WM-180**

## **Appendix B**

### **Development of Action Levels for the HWMA/RCRA Closure of Tank WM-180**

The INTEC TFF Tank WM-180 is to be closed under HWMA (State of Idaho 1983)/RCRA (42 USC 6901 et seq., 1976) by removal of the waste currently contained in the tank and decontamination of the internal tank surfaces. Compliance with the performance standard for closure of tank systems (40 CFR 265.111 and 265.197) is to be demonstrated for the tank by sampling the final rinsate solutions from the decontamination efforts and comparing the resulting analytical data with ALs developed in this appendix. The ALs for the HWMA/RCRA closure of Tank WM-180 has been developed to ensure that the tank, subsequent to completion of closure activities, will be left in a state that is protective of human health and the environment. This appendix was prepared to present the methodology used to develop ALs specific to the HWMA/RCRA closure of Tank WM-180. The ALs were developed by defining the acceptable excess cancer risk and hazard quotient thresholds and calculating corresponding ALs based upon these risk and hazard thresholds. Finally, the excess cancer risk and hazard for all pathways and contaminants at the developed ALs are presented. The technique for calculation of ALs described in this appendix will be applied to any additional chains of custody identified during the course of closure activities for Tank WM-180.

This analysis considers two pathways: soil inhalation and soil ingestion to an occupational receptor. Performing the analysis considering these pathways is very conservative. The EPA guidance (EPA 1989) states that the soil inhalation and soil ingestion pathways are appropriate for soil contamination not greater than 10 ft in depth. While the potential soil contamination resulting from liquid contacting the internal tank surfaces will be greater than 40 ft in depth, these pathways were retained to ensure the protectiveness of the AL development methodology. In developing the conceptual site model for this risk assessment, the following assumptions were made:

1. Liquid infiltration contacts the internal tank surfaces
2. Contacting liquid then exits the tank system with all contaminants of concern (COC) present at AL concentrations
3. Each liter of contaminated liquid contaminates 1 kg of soil (thus each part per million of contaminant in the liquid is equivalent to one part per million of contaminant in the soil).

Assumption No. 1 is conservative due to the planned grouting of the tank system. Once the tank has been grouted, it is highly unlikely that water infiltration will contact the internal tank surfaces. Assumption No. 2 is conservative because it assumes immediate release of liquid contacting the internal tank surfaces from the tank to the soil (should such liquid/tank surface contact be possible, which is unlikely due to grouting). In reality, liquid contacting the internal tank surfaces will remain contained within the stainless steel tank and concrete vault. Assumption No. 3 is conservative for three reasons. First, assuming an average bulk soil density of 1.3 kg/L, and an average soil porosity of 0.45, the void volume in a typical kilogram of soil is approximately 350 mL. Thus, although the assumption has been made that each liter of contaminated liquid contaminates 1 kg of soil, in reality, it is only physically possible for 350 mL of the contaminated liquid to contaminate each kilogram of soil. Second, it is assumed that the liquid and soil are in contact for sufficient time to allow mass transfer equilibrium to be reached between the soil column and the liquid, whereas in reality, the water will be flowing through the soil column and equilibrium will not be reached. Finally, it is assumed that 100% of the contaminant is transferred to the soil without regard for partitioning of the contaminant between the soil column and the

water. In reality, a fraction of each of the contaminants will remain contained within the contaminated liquid.

## **Step 1: Define the Total Allowable Excess Cancer Risk and Hazard Quotient to the Future Occupational Receptor**

As stated in the assumptions above, the liquid that may come into contact with the closed tank system and subsequently contaminate surrounding soil is assumed to exit the tank system and enter the surrounding soil at the AL concentration. The surrounding soil is then assumed to be contaminated at equivalent parts per million concentrations. Consequently, risk-based media cleanup standards are appropriate to establish the allowable excess cancer risk and hazard quotient. Protective media cleanup standards for human health means constituent concentrations that result in the total residual risk from a medium to an individual exposed over a lifetime falling within a range from  $10^{-4}$  to  $10^{-6}$ , with a cumulative carcinogenic risk range. For noncarcinogenic effects, EPA generally interprets protective cleanup standards to mean constituent concentration that an individual could be exposed to on a daily basis without appreciable risk of deleterious effect during a lifetime; the hazard index generally should not exceed 1 (55 FR 46, 1990; 55 FR 145, 1990; 61 FR 85, 1996). To ensure protectiveness of human health, the most conservative threshold for excess cancer risk,  $1.0\text{E-}06$ , will be used for Tank WM-180. Therefore:

- Total allowable risk threshold =  $1.0\text{E-}06$
- Total allowable hazard quotient threshold = 1.0.

## **Step 2: Define Receptors and Pathways**

The pathways considered for developing ALs include:

- Occupational receptor ingestion of contaminated soil
- Occupational receptor inhalation of contaminated soil.

## **Step 3: Define Contaminants of Concern and Toxicity Parameters**

The COC list was developed by defining all HWMA/RCRA-regulated constituents that meet either of the following criteria:

1. The HWMA/RCRA-regulated constituent was detected during sampling and analysis of the waste currently contained within Tanks WM-182 and WM-183 *and* the constituent is listed in the EPA Region 9 preliminary remediation goal (PRG) table (EPA 2003)<sup>a</sup>
2. The HWMA/RCRA-regulated constituent was determined to be part of the INTEC liquid waste stream as described in *A Regulatory Analysis and Reassessment of U.S. Environmental Protection Agency Listed Hazardous Waste Number for Applicability to the INTEC Liquid Waste System* (Gilbert and Venneman 1999).

---

a. One constituent, 2-hexanone, while not listed in the EPA Region 9 PRG Table, was listed in the EPA Region III Risk-Based Concentration Table (EPA 2002). This constituent was retained in the COC list, and toxicity information from the Region III document was used to determine constituent-specific action levels for 2-hexanone.

Applying the two criteria defined above allows definition of the complete COC list for HWMA/RCRA closure of Tank WM-180. The complete list of COCs is provided in Table B-1. As stated in Criterion No. 1, above, detected constituents that are not listed in the EPA Region 9 PRG table were excluded from the COC list. Constituents excluded for this reason were calcium, chloride, magnesium, nitrate, phosphate, and sulfate.

Reference doses (RfDs) and slope factors (SFs) for each of the COCs are provided in Table B-1. This information was obtained from the EPA Region 9 PRG table (EPA 2003). Toxicity information for 2-hexanone was obtained from the EPA Region III risk-based concentration table (EPA 2002). The EPA Region 9 PRG table does not include inhalation RfDs for antimony, arsenic, cadmium, and chromium. As requested by the IDEQ, the ingestion RfDs for these four metals were used as both ingestion and inhalation RfDs. Toxicity information is available for all COCs listed in Table B-1 with the exception of lead. While there is no specific toxicity information currently available for lead, separate EPA guidance was used to develop the AL for lead (see Step 8).

The COC list for this closure includes phenol, which was detected during confirmation sampling of Tank WM-182. Phenol was added to the AL list and included in the calculation of ALs.

Table B-1. COCs and toxicity parameters as provided in the EPA Region 9 PRG table (EPA 2003).

a. The toxicity information was obtained from the EPA Region III risk-based concentration table (EPA 2002).

b. The ingestion RfD is used as the inhalation RfD although no inhalation RfD is provided in the EPA Region 9 PRG table (EPA 2003).

### Step 4: Define Percentage of Risk and Hazard to be Applied to Ingestion and Inhalation Scenario

The total allowable excess cancer risk and hazard quotient must be split into the fraction that is allowable for the ingestion pathway and the fraction that is allowable for the inhalation pathway. Experience indicates that the ingestion pathway will drive the risk and hazard for the occupational receptor. Consequently, the majority (99.5%) of the allowable risk and hazard defined in Step 1 above was assigned to the ingestion pathway as shown in Table B-2.

Table B-2. Pathway-specific allowable risk and hazard.

	Total	Ingestion (%)	Inhalation (%)	Ingestion Fraction	Inhalation Fraction
Risk	1.00E-06	99.5	0.5	9.95E-07	5.00E-09
Hazard quotient	1.00E+00	99.5	0.5	9.95E-01	5.00E-03

### Step 5: Calculate the COC-Specific Allowable Risk and Hazard Quotient for Each Pathway

Back-calculation of ALs for COCs requires determination of allowable risk for each COC.<sup>b</sup> The sum of all allowable risks must be less than 1.0E-06. To determine the allowable risk for each COC, the total allowable risk must be apportioned among the COCs. There are several techniques for apportioning allowable risk among COCs.

b. While this discussion of apportioning risk among COCs is written with respect to determination of action levels using carcinogenic contaminants and risk-based back-calculation, it applies equally to determination of action levels using noncarcinogenic contaminants and hazard-based back-calculation.

The simplest technique for apportioning allowable risk is to distribute allowable risk equally among the COCs. Using this technique, the allowable risk is divided by the total number of carcinogenic COCs and the result is used as the allowable risk for each COC. The problem with this approach is that it makes no differentiation among COCs with respect to carcinogenic threat to human health. In the case of the AL determination for the HWMA/RCRA closure of Tank WM-180, the same allowable risk is assigned to a COC that is extremely carcinogenic (N-nitrosodimethylamine [SF 51 (mg/kg-d)<sup>-1</sup>]) and a contaminant that is minimally carcinogenic (chloroethane [SF 0.0029 (mg/kg-d)<sup>-1</sup>]). Using this approach results in ALs that are extremely low (below detection levels in many instances) for the highly carcinogenic compounds and ALs that are excessively high for minimally carcinogenic compounds. This approach results in decontamination efforts being driven by the need to meet a single AL for the most carcinogenic component. The actual COC concentrations for the less carcinogenic components will be reduced far below ALs, resulting in a total residual risk far below the threshold of 1.0E-06. While extremely conservative, this approach results in ALs that may prove impossible to achieve during closure (particularly those below detection limits).

A second approach uses SF normalization to apportion allowable risk among the COCs. The SFs for all carcinogenic COCs are summed, and the percent SF contribution to the total is used to determine the percent of the allowable risk that is apportioned to each COC. In this way, the majority of the allowable risk is assigned to the COCs that are the most highly carcinogenic. This technique is superior to the equal distribution technique described above because it results in ALs for highly carcinogenic contaminants that are above detection limits and realistically achievable, while still maintaining the overall allowable risk below the regulatory threshold. The problem with this approach for the purposes of determining ALs for the closure of Tank WM-180 is the presence of the extremely carcinogenic N-nitrosodimethylamine. This contaminant is extremely carcinogenic with respect to the other COCs present in the tank system. Using the normalization approach, consequently, results in the majority of the allowable risk being assigned to this contaminant. This results in greatly reduced ALs for moderately carcinogenic contaminants such as heavy metals. This approach results in decontamination efforts being driven by the need to meet ALs for the metals. Due to the chemistry associated with the contents of the tank, and the relative ease of decontaminating organic contaminants versus metals, decontamination to meet the ALs for metals will result in actual concentrations of organic constituents that will be far below the ALs for these constituents. This would result in a total residual risk far below the threshold of 1.0E-06. This approach results in ALs for various metals that may prove impossible to achieve during closure.

While both approaches described above result in ALs that are compliant with the need to reduce risk below 1.0E-06, the first approach results in an impracticable AL for the highly carcinogenic N-nitrosodimethylamine. The second approach results in impracticable ALs for a variety of heavy metals. A compromise approach balancing the ALs for the amine and the metals to achievable, yet protective, levels was developed. This third approach uses logarithmic SF normalization to apportion allowable risk among the COCs. A normalizing power of 0.5 was selected via trial and error that resulted in achievable, yet compliant ALs for all COCs. Each of the SFs was raised to the power of 0.5. These SFs were then summed, and the percent contribution to this sum of each SF was determined. This percent contribution was then used to assign allowable risk to all carcinogenic COCs.

The three approaches above are alternate methods for assigning allowable risk to each COC. The sum of the allowable risk for each approach is the same, at 1.0E-06. Selection of the third technique provides ALs that are technically practicable. The true risk resulting from each COC is calculated in Step 7 of this methodology. This true risk is calculated at 9.2E-07, demonstrating that the selected ALs are compliant with the regulatory threshold of 1.0E-06. The calculation of true residual risk is independent of the apportioning of allowable risk performed in this step.

As discussed above, allowable risk and hazard quotients for each COC for each pathway were normalized logarithmically against their expected percent contribution to the overall risk and hazard for each pathway. For carcinogenic risk, the square root of the SF for each COC was determined. The normalized SF percentage was determined by dividing the square root of the SF for each COC by the sum of the square root of the SFs for all COCs for a given pathway. This percent contribution was then multiplied by the total pathway-specific allowable risk to calculate the COC- and pathway-specific allowable risk. To increase the conservativeness of the design, correction factors (discussed below) were applied to COCs, as necessary, to reduce the total allowable risk for each COC. The resulting COC pathway-specific allowable risks for ingestion and inhalation are listed in Table B-3.

For noncarcinogenic hazard, the square root of the inverse of the RfD for each COC was determined. The normalized inverse RfD percentage was determined by dividing the square root of the inverse RfD for each COC by the sum of the square root of the inverse RfDs for all COCs for a given pathway. This percent contribution was then multiplied by the total pathway-specific allowable hazard to calculate the COC- and pathway-specific allowable hazard. To increase the conservativeness of the design, correction factors (discussed below) were applied to COCs, as necessary, to reduce the total allowable hazard for each COC. The resulting COC pathway-specific allowable hazard for ingestion and inhalation are listed in Table B-3.

Table B-3. COC-specific allowable risk and hazard for the soil ingestion and inhalation pathways.

COC	Effective Allowable Ingestion Risk	Effective Allowable Inhalation Risk	Effective Allowable Ingestion Hazard	Effective Allowable Inhalation Hazard

Correction factors were used in the risk calculations to lower the ALs of contaminants to meet regulatory thresholds. Risk calculations alone would produce concentrations greater than the maximum concentration of contaminants for the toxicity characteristic. Correction factors, therefore, were used to augment the risk number to ensure hazardous waste is not left in place. Removing hazardous waste is the first criteria for achieving clean closure for the tank system.

In an effort to develop ALs at appropriate concentrations and meet project goals for protection of the public and the environment, correction factors were developed on a case-by-case basis and may vary for different tank systems. Systems that are fairly accessible and with contamination that can be removed to low concentrations will have different correction factors than those used for tank systems that are not easily accessible and where effective decontamination may be more difficult to achieve. Two important points should be recognized:

- Correction factors are not intended to be the same for all closure actions. Therefore, DOE can develop ALs as conservative as possible on a project basis.
- The ALs will always be protective of human health and the environment based on the calculated risks and hazard index.

The use of correction factors is performed to lower ALs to concentrations below regulatory thresholds while accounting for project-specific challenges to clean closure. The correction factors are not used to adjust for the uncertainty of any closure project. The difference between the use of correction factors and accounting for uncertainty is clearly established by the following explanation.

Using conservative assumptions when calculating the risk and hazard quotient negates uncertainties associated with meeting the performance standard for clean closure. Examples of the conservative assumptions used in AL calculation are listed below:

- Risk and hazard indices are based on the total number of constituents that may be detected in the unit. Actually, some of these constituents (particularly organic compounds) will not be present after waste removal and decontamination. For example N-nitrosodimethylamine is a significant contributor to risk. However, it is likely that this compound will not be detected during final

sampling. The total risk will then be reduced by the amount contributed by N-nitrosodimethylamine. The calculated risk for N-nitrosodimethylamine from soil ingestion and inhalation is 6.48E-07. This is the greatest potential risk contributor in Tank WM-180.

- The probability of detecting N-nitrosodimethylamine after decontamination is based on the decontamination factor that is necessary to reduce the maximum detected concentration to one that is below the detection limit. This decontamination factor is approximately 15. While the decontamination factor for reducing the concentration of mercury to below the AL is more than 100. The relationship between the two decontamination factors indicates N-nitrosodimethylamine will likely be completely removed.

## Step 6: Calculate the COC- and Pathway-Specific Action Levels from Allowable Risk and Hazard Calculated in Step 5

The equations used to relate risk, intake factor, and SF or RfD to excess cancer risk or hazard quotient are given in Step 7. These equations were obtained from EPA guidance (EPA 1989). The risk-based COC-specific ALs were calculated from COC-specific allowable risk by dividing the COC-specific allowable risk (see Table B-3) by the intake factor coefficient (see Step 7) and the COC-specific SF (see Table B-1). The hazard-based COC-specific ALs were calculated from COC-specific allowable hazard quotients by dividing the COC-specific allowable hazard quotient (see Table B-3) by the intake factor coefficient (see Step 7) and multiplying by the RfD (see Table B-1). The COC-specific ALs for the ingestion and inhalation pathways resulting from COC-specific allowable risk and COC-specific allowable hazard are listed in Table B-4. To be conservative, the minimum pathway-specific AL was used as the overall AL. The final effective ALs are provided in the right-hand column of Table B-4.

Table B-4. Pathway-specific and effective action levels for each COC.

COC	Action Level (mg/Kg) Ingestion Risk	Action Level (mg/Kg) Inhalation Risk	Action Level (mg/Kg) Ingestion Hazard	Action Level (mg/Kg) Inhalation Hazard	Effective Action Level (mg/Kg)

a. The AL for lead cannot be determined using a risk-based approach, as there are currently no established toxicity parameters for lead. The AL for lead was developed as described in Step 8.

## Step 7: Determine the True Excess Cancer Risk and Hazard Quotient Resulting in the Action Levels Calculated in Step 7

Soil concentrations resulting from the calculated ALs were used as a starting point to assess the risk and hazard to the occupational receptor via the soil ingestion and inhalation pathways. The results of this analysis are provided in Table B-5. The table also includes the cumulative risk and hazard posed by both pathways. The calculation spreadsheets are shown on the following pages in Equations (B-1) through (B-9) and Tables B-6 through B-9.

Table B-5. Cumulative excess cancer risk resulting from soil ingestion and soil inhalation pathways to an occupational receptor from contaminated soil at the effective action levels presented in Table B-4.

COC	Risk (Ingestion Pathway)	Risk (Inhalation Pathway)	Total Risk	Hazard Quotient (Ingestion Pathway)	Hazard Quotient (Inhalation Pathway)	Total Hazard Quotient

## Occupational Soil Ingestion

$$Intake\ Factor = \left( \frac{C \times FI \times EF \times CF}{AT} \right) \times \left( \frac{IR \times ED}{BW} \right) \quad (B-1)$$

where

$C$  = contaminant concentration (mg/kg) (contaminant dependent)

$FI$  = fraction ingested from source = 1

$EF$  = exposure frequency (day/year) = 250

$CF$  = conversion factor (kg/mg) = 1.00E-06

$AT$  = averaging time (day) = 2.55E+04

$IR$  = ingestion rate (mg/day) = 50

$ED$  = exposure duration (year) = 25

$BW$  = body weight (kg) = 70.

**Assumption: Each liter of leachate contaminates 1 kg of soil.**

$$Risk = Intake\ Factor \times Slope\ Factor \quad (B-2)$$

Table B-6. Calculation of excess cancer risk for an occupational soil ingestion scenario using the action levels provided in Table B-4.

Constituent	C (mg/Kg)	Intake Factor/C (1/day)	Intake Factor (mg/Kg- day)	Slope Factor (Kg- day/mg)	Risk	Risk Percentage

## Occupational Soil Inhalation

$$Intake\ Factor = \left( \frac{C \times IR \times EF \times ET \times ED}{BW \times AT \times PEF} \right) \quad (B-3)$$

where

$C$  = soil contaminant concentration (mg/kg) (contaminant dependent)

$IR$  = inhalation rate (m<sup>3</sup>/hr) = 0.83

$EF$  = exposure frequency (day/year) = 250

$ET$  = exposure time (hour/day) = 8

$ED$  = exposure duration (year) = 25

$BW$  = body weight (kg) = 70

$AT$  = averaging time (day) = 2.55E+04

$PEF$  = particulate emission factor (m<sup>3</sup>/kg) (calculated).

$$PEF = \frac{LS \times 5.8E+10}{A} \left( \frac{m^4}{kg} \right) \quad (B-4)$$

where

$LS$  = prevailing wind field dimension (m) = 49.65

$A$  = area of contamination (m<sup>2</sup>) = 1140.15.

**Assumption: Each liter of leachate contaminates 1 kg of soil.**

$$Risk = Intake\ Factor \times Slope\ Factor \quad (B-5)$$

Table B-7. Calculation of excess cancer risk for an occupational soil inhalation scenario using the action levels provided in Table B-4.

## Step 8: Determine an Action Level for Lead

Of the COCs currently applicable to Tank WM-180, only lead does not have a RfD or a SF. The following discussion offers an approach for establishing an AL for lead. Soil screening guidance (EPA 2001) suggests a lead soil concentration of 400 mg/kg based on *Revised Interim Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities* (EPA 1994). The liquid lead concentration is calculated using the definition of  $K_d$ . The  $K_d$  value is the ratio of the soil concentration to the liquid concentration. Thus, the AL is calculated by dividing the suggested soil concentration for lead by the  $K_d$ . The  $K_d$  of lead is 100 cm<sup>3</sup>/g (EPA 1996). With these values, lead AL is calculated at 4 mg/L.

**Appendix D**

**Statistical Analysis for Tank Farm Closure**

## Appendix D

### Statistical Analysis for Tank Farm Closure

#### D-1. INTRODUCTION

Several different statistical methods will be applied to the TFF closure data. The primary objective with regard to the statistical analysis that will be performed on the data is to determine if the constituents of interest are present in levels greater than the specified action level. Confidence intervals will be used for this analysis. Five samples will be taken from Tank WM-180 and one sample from the WM-180 vault sump. This provides a total of six samples from Tank WM-180.

#### D-2. CONFIDENCE INTERVALS

Confidence intervals will be used to determine if any of the constituents of concern in the tank or the WM-180 vault exceed the specified action levels. This is done by constructing a 90% confidence interval for the concentration of each constituent in the tank and comparing the upper confidence limit with the specified action level. If the upper confidence limit is less than the action level, then the constituent is considered to be present in levels less than the action level. If the upper confidence limit is greater than the action level, then it is assumed that the constituent is present in concentrations that are greater than the action level and appropriate action will be taken.

##### D-2.1 Construction of a Confidence Interval

A confidence interval is constructed using the sample mean and standard deviation of the data. For each constituent, the mean concentration,  $\bar{X}$ , is calculated using Equation (D-1)

$$\bar{X} = \frac{\sum_{i=1}^n X_i}{n} \quad (D-1)$$

where

$n$  = the number of observations in the data set

$X_i$  = the  $i^{th}$  observation in the data set.

The standard deviation,  $s$ , is calculated using Equation (D-2)

$$s^2 = \frac{\sum_{i=1}^n (X_i - \bar{X})^2}{n - 1} \quad (D-2)$$

The confidence interval is calculated using the expression

$$\bar{X} \pm t_{1-\alpha, n-1} \sqrt{\frac{s^2}{n}}$$

where

$t_{1-\alpha, n-1}$  = the  $t$ -statistic at  $1-\alpha$  with  $n-1$  degrees of freedom

So

$$UCL = \bar{X} + t_{1-\alpha, n-1} \sqrt{\frac{s^2}{n}} \quad (D-3)$$

where

$UCL$  = upper confidence limit.

The  $t$ -statistic can be found on a  $t$ -table or from a statistical software package. In the case of the analysis for the TFF closure,  $\alpha = 0.05$  since the 95% upper confidence limit is being used. This is the significance level of a statistical hypothesis test. Essentially comparing the upper limit of a confidence interval to the action level is comparable to performing a one-sample  $t$ -test of the sample mean against the action level at the  $\alpha = 0.05$  level. (The 95% upper confidence limit is the upper limit of a 90% confidence interval. Since it is only the upper confidence limit that is being compared to the action level, setting  $\alpha=0.05$  gives the test an overall significance level of 0.05.)

## D-2.2 Use of the Confidence Interval

Once the confidence interval has been calculated for a given constituent concentration, a comparison can be made against the action level for that constituent. The general rule is if

$$\bar{X} + t_{1-\alpha, n-1} s < AL \quad (D-4)$$

where

$AL$  = action level

then it can be confidently concluded that the constituent concentration is less than the action level. However, if

$$\bar{X} + t_{1-\alpha, n-1} s \geq AL \quad (D-5)$$

then it cannot be concluded that the constituent concentration is less than the action level. In this situation, it is assumed that the constituent concentration exceeds the action level and the appropriate action should be taken.

A confidence interval will be constructed for every constituent of concern in the tank and in the vault sumps for the tank. This means if there are 10 constituents of interest, 40 confidence limits will be calculated and compared to the appropriate action levels.

Let's work through an example calculation to determine the 95% upper confidence limit. If the sample data are  $\bar{X} = 0.87$ ,  $s^2 = 0.073$ ,  $t_{0.05,9} = 1.833$ , and  $UCL = 0.87 \pm 0.1565$ , which corresponds to an upper confidence limit at 1.03 mg/L, then the calculation yields the following:

Liquid Arsenic Sample Data (Example)			
Sample No.	Concentration (mg/L)	Sample No.	Concentration (mg/L)
1	0.79	6	0.98
2	0.85	7	0.87
3	0.92	8	0.78
4	0.75	9	0.88
5	0.80	10	1.06

Since the action level for liquid arsenic has been set at 1.05, it can be determined that for these 10 samples, there is 95% confidence that the true mean is less than 1.03 mg/L. This method is adapted from *Test Methods for Evaluating Solid Wastes, Physical/Chemical Methods* EPA SW-846 (1998).

### D-2.3 Assumptions of Confidence Intervals

When constructing a confidence interval, the data must be approximately normally distributed to meet the assumptions of the confidence interval. Since the  $t$ -statistic is used to generate the confidence interval, the interval is robust against certain variations from the normal distribution. However, the data still need to be symmetric about the mean and free of outliers. Since the  $t$ -statistic is robust against slight variations from the normal distribution, performing a hypothesis test to verify the normality of the data is not appropriate. Statistical tests that are used to determine if a data set follows a certain distribution are highly sensitive to variations of the data from the distribution in question. Because of this, data that fail to meet the requirements of the statistical test for normality may still produce a reliable confidence interval. In fact, if a statistical test for determining the normality of the data does show that the data are normal (i.e., the null hypothesis is not rejected), then the  $z$ -statistic should be used in the confidence interval instead of the  $t$ -statistic. The normality of the data can be better assessed by examining the summary statistics of the data and through graphical methods such as histograms.

Another assumption that is made when constructing a confidence interval is that the sample mean and the standard deviation are independent. This is always the case if the data are truly normally distributed. Because of this, it is assumed that this assumption is met if the data appear to be approximately normally distributed.

### D-2.4 Using the Lognormal Transformation

Since the type of data that will be obtained from the TFF tanks is non-negative, it is likely that the data will be log normally distributed rather than normally distributed. This means that the natural log of the data points have a normal distribution. The traditional method for analyzing lognormal data is to take the log of all of the data points and perform the statistical analysis on the transformed data. Any methods that are appropriate for the normal distribution can be applied to the transformed data. However, this can pose some complications with some analytical methods. For example, a confidence interval that is generated using the transformed data is accurate for estimating the mean of the transformed data, but the interval cannot be transformed back to the scale of the raw data to estimate the mean of the raw data.

However, the  $t$ -test can be accurately performed on the transformed data against a cutoff value such as the action level of a constituent. The test is performed by taking the log of the raw data and calculating the mean and standard deviation using the transformed data. These values are then used to perform a  $t$ -test against the log of the action level. Because the confidence interval is only being used to conduct a  $t$ -test for the data from the TFF, the results obtained by comparing the 95% upper confidence limit of log transformed data against the log of the action level is as accurate a test as comparing the 95% upper confidence limit against the action level if the raw data were truly normally distributed.

It is possible that the data that will be obtained from the TFF will be neither normal nor log normally distributed. If this is the case, other transformations will be attempted on the data to see if normality can be achieved with some transformation. The methods described above will be applied to the transformed data. As with the natural log transformation of the data, confidence intervals can be used to perform a  $t$ -test on the transformed data.
